This leads us to consider the speaker’s role in a situation as bound by social and other convention; any speech act (see below) that is uttered during a negotiation situation can only have the force that is allowed it, based on the speaker’s social and institutional placement. Conversely, such a voicing of the situation can itself contribute to the establishment of a powerful or power-like situation; words and actions interact dialectically with contexts and situations. Consider the following case, adapted from the Swiss novelist Friedrich Dürrenmatt’s short story *The breakdown* (Dürrenmatt, 1956).

In the story, a traveling salesman meets three people in the dining room of a hotel in the little provincial town where he has to spend the night because his car has broken down. For some reason, the three gentlemen seem to be happy to see him, and invite him for a late supper at the home of one of their number. During and after the meal, the conversation focuses more and more on the hosts’ past occupations of attorney general, judge, and trial lawyer, respectively. In the end, the trio enacts a mock court session in which the traveling salesman (who by now has lost all sense of time and space) is condemned to the severest penalties for his past misdeeds.

What is interesting here is the way in which, by force of their earlier societal standing, the three men manage to create the illusion of a court session in which the accused ends up confessing his crimes and accepting his sentence. The relevance of Dürrenmatt’s legal game is that it shows us how the law is not only embodied in institutional roles and legal language, but depends on the social environment, the context in which that language is practiced. The hapless traveler who fell into the clutches of the quasi-practicing legal trio was every bit as damned as he would have been had he been condemned by a regular court.

Societally institutionalized speech acts were among the first to be discovered by Austin (1962). (See **Austin, John L.**) The concept of the social context has been valuable not only as a classificatory criterion, but also because it makes us look at what speech acts

really do, and how they are able to do what they do, as we will see below. In our example, the speech act of sentencing not only brought about a changed state of affairs (the sentenced person was supposed to go to jail), but it also (re-)created the legal system whose reality it confirmed (by the pronouncing of the sentence). Not only does the social context allow for and determine what is appropriate speech acting in the context, it is itself construed through the use of the appropriate language: societal institutions are (re-)instituted through the use of speech acts. This is the social, psychological, and above all pragmatic significance of the practical joke perpetrated on the poor traveler in the Dürrenmatt story.

Speech and Speech Acts

Above, I mentioned John L. Austin, the Oxford philosopher, as one of the great sources of inspiration for our modern thinking on how language works, or on “how to do things with words,” in Austin’s own immortal formulation (1962). Austin’s contribution is linked to the concept of the speech act, a use of language that not only says, but does. The idea is of course not new: many of us are familiar with the institution of the religious sacrament (such as the Christian baptism). Here, the notion that a formula (such as used in administering baptism) works in force of the words spoken (“I baptize thee”), in tandem with the action performed (letting water flow across the baptizée’s head). That the sacral action is performed as denoted by the words is at the basis of the belief according to which the sacrament is effective, not by force of the sayer, but by force of the words spoken and the act done. In Catholic theology, this aspect of the action goes by the label of *ex opere operato* ‘in force of the act that is performed’; in speech act theory we talk about an aspect of a speech act, the performative or perlocutionary effect, that comes in addition to the words spoken (the locutionary aspect) and the point of the act (the illocutionary aspect), which makes it into precisely this act and no other (see **Speech Acts and Grammar**).

For Austin, speech acts could be distinguished and neatly labeled according to their ‘point’ or illocutionary force: ordering, asserting, requesting, and so forth. Austin’s student John R. Searle, who later went back to the United States and taught at Berkeley, systematized and extended Austin’s classification of speech acts and in particular, systematized the conditions that would make a speech act legal and effective (rather than ‘misfiring,’ as Austin called it, e.g., when the person executing an institutional act such as a marriage ceremony does not have the

necessary credentials). These felicity conditions, as they often are called, comprise such matters as the agent’s sincerity (e.g., in proffering a promise), the agent’s or recipient’s ability to be acted upon (in our society, a person cannot be legally married a second time as long as his or her first marriage is in force), and so on. Searle’s merit is to have systematized not only Austin’s speech acts, but in particular to have perfected his assignment of the conditions that must be met before a speech act can be said to be valid (see **Speech Acts**).

But there is more to this than meet the eye (or the act). Unfortunately, Searle not only developed Austin, but in doing so technologized him (Melrose, 1996: 61–62). Searle’s main interest was not how to do things with words, but how to systematize and describe the words that do those things, the speech acts as such. It may be said about Austin that he never was overly technical about his speech acts – something which earned him scorn from later speech act theorists (Mey, 2001: 117–118). In Austin’s original thinking, it is the words that have to be “to some extent ‘explained’ by the ‘context’ in which they have been actually spoken” (Austin, 1962: 100; the scare quotes are Austin’s own). Austin is interested in the context because he wanted to “study the total speech in the total situation” (Austin, 1962: 148), which is exactly what pragmatics is all about. Whereas Austin was doing things with words, Searle is describing acts of speech.

The Problem of the Indirect Speech Act

For Austin and many of his followers, a speech act is primarily expressed by what is called a speech act verb, that is, a verb whose main function is to signal and execute the appropriate act. For instance, when I say *I promise*, the verb *to promise* is the appropriate (sometimes called canonical) expression for this particular act (see **Speech Acts and Grammar**).

Early on, it was noticed that many speech acts are performed successfully without the help of the canonical verb. For instance, I can confirm a promise, or even make one, by simply saying what I’m going to do, or by uttering an affirmative reply to a question. The most outstanding example of a solemn promise (a vow) that does not use the verb *to promise* is when man and wife promise each other to be faithful and supportive *until death doth them part*. The promise is uttered by the auxiliary (or tag) verb ‘to do’ (a tag verb is one that repeats the tagged portion of the main verb construction, as in *Do you...? Yes I do*).

More generally, the appropriate speech act can be expressed by reference to one of the conditions

that Austin and Searle stipulated as necessary for successfully performing such an act. One can, for example, inquire about a person's ability to give information or perform a task, as in *Can you tell me the time?* or *Could you close that window?* In such cases, the inquiry is understood not as a mere preliminary to a request for information or action, but as the act itself of asking for information or requesting a favor, respectively. Such acts are called indirect, since they lead the addressee to infer, from the fact that a request was formulated regarding an ability or willingness, that the request in fact was about the object of the ability or willingness (in this case, to give out information or to close a window).

Interestingly, contrary to what seemed to be the original motivation behind classifying speech acts and speech act verbs, the indirect way of doing things with words is, in many cases, the preferred one. I have called this phenomenon the 'indirect speech act paradox' (Mey, 2001; see **Pragmatic Acts**); it is confirmed by observations such as that by Levinson (1983) that "most usages of requests are indirect," whereas such speech as orders are seldom, if ever, executed by the canonical verb form, the imperative mood: "imperatives are rarely used to command or request" (Levinson, 1983: 264, 275; see further Mey, 2001: 111). A particular use of indirectness in speech acting is found in the phenomenon called inferring by implicature; more on this below.

Indexing and Inferring

To get a handle on the phenomenon of inference, let's first consider the use of what linguists call deictic elements. These are words and expressions that directly refer to persons, objects, situations, etc. by 'pointing' to them, using what is called *deixis* (the Greek word for 'pointing to, indicating'; the human forefinger is called 'index' because it is our first and foremost natural pointing instrument). Thus, when I say *I* about myself, I point to the person that I am; *you* points to the person away from me, *viz.*, an actual or potential interlocutor (see **Deixis and Anaphora: Pragmatic Approaches**).

Most languages have a more or less elaborate system of such 'pointers' that help us identify persons and situations when we are interacting verbally and otherwise. We can refer to a book that is mine, as 'this book,' whereas a book that is yours, or in your possession, may be called 'your book' or 'that book.' But deictics have other functions as well. 'That' can also express contempt (*that son of a bitch*) or respect (*gimme that old time religion*). Moreover, such 'indexing' can happen even without my knowing

or willing, as when "my speech betrays me": the language I speak reveals ('indexes') (see **Indexicality: Theory**) my social or local roots, as happened for St. Peter in the famous betrayal scene, after he had three times publicly denied having ever set eyes on "that man," Jesus of Nazareth (Matt. 27:70–72).

Conversely, we can use this kind of indexing to provoke a reaction in our interlocutors. For instance, using high-falutin language and 'expensive' words can create an impression of scholarship and learning. When I doctor my speech to create such a (possibly false) impression, I base myself on the hopeful assumption that people who hear this particular kind of language will infer that I indeed belong to the class of educated people (alternatively, they may infer that I am a terrible snob).

As in the case of the indirect speech acts, what is said is not the whole story. Based on my actual knowledge of the world and the input from my interlocutors, I make certain inferences, albeit indirectly and perhaps not always convincingly and/or justifiably. The main point is that we are able to communicate certain thoughts or feelings, using indirect means and relying on the common world situation (or scene) that we are part of.

We imply certain things about ourselves and the world when we use deictics and other indexicals in this way; our interlocutors are supposed to make the proper inferences in order to successfully understand us or communicate with us. That such an understanding may be wrong, or even willfully distorted, is one of the secrets of the successful mystery or detective story; the innocent reader is led down a 'garden path' of false inferences, to be suddenly confronted with the real state of affairs in a moment of truth.

As an example, consider the Argentine writer Julio Cortázar's 'Story with spiders' (*Historia con migalas*; Cortázar, 1984), in which the readers are made to believe certain things about a couple vacationing on an island in the Caribbean. The sinister impact of their activities and the relationship to their earlier exploits of the same murderous kind is hinted at in the very last lines of the narrative, when the couple is unmasked as a nefarious, female duo bent on destroying men (hence the title word 'spiders,' which contains an important, but not sufficient clue). What the author does here is to play on our implicit understanding of the language (in Spanish as in English, the default couple is male plus female), in order to have us infer the normalcy of the situation, only to shock us back into the real world when the identity of the spiders is revealed, again by the use of an indexical element: a female adjectival ending. Only then do we infer the couple's identity; the rest of the

gruesome inferences are left to our imagination and our ability to put two and two together on the basis of clues provided earlier. (A complete analysis of this intriguing piece of text is given in Mey, 1992) (see **Literary Pragmatics**.)

Next, we will discuss a particular way of implying, and see how proper inferences may be drawn using the notion of cooperation. (On inferring vs. implying, see Thomas, 1996: 58–59).

Cooperating and Implying

A pragmatic view of language bases itself, as we have seen, on the ways speakers and hearers are able to communicate in a given situation. A very important factor in this is the speakers' willingness to enter the situation with a decision to cooperate with their partners. The Berkeley philosopher H. Paul Grice (see **Grice, Herbert Paul**) is famous for having formulated the Cooperative Principle, stating the human need for, and extent of, cooperation in conversation, a principle that he detailed further in the four so-called conversational maxims, which guide the speakers and hearers through the conversational maze in a mutually satisfying way (see Mey, 2001: 71ff) (see **Cooperative Principle**).

The fact that cooperation is, so to speak, built into the very marrow of conversation makes us prepared to accept what is offered in conversational exchange, as being of relevance to our needs and interests. If I ask somebody for the time of day, I take it that he or she will cooperate and tell me the time, and not make some completely ludicrous remark about the state of the world. Or, "What man of you, if his son asks him for bread, will give him a stone?" as the Gospel tells us (Matt. 7:9). Conversely, we may make our intentions clear by precisely not answering a question in the expected way, or not fulfilling a reasonable request. If the father did give his son a stone for bread, he probably wanted to tell him something about the way the world is organized: people taking advantage of each other, even cheating on each other. However, in a more subtle way I can use this indirectness to appeal to an understanding of the situation that is built into the very question, so to speak. The innocent question *What time is it?* can correctly and satisfactorily be answered indirectly by referring to an event that both interlocutors know as denoting a particular time. In my Norwegian house, where we had very little traffic on the county road passing by our house, the utterance: *The bus just went by* would be a completely happy answer to a request for the correct time: there was only one bus a day, and it passed our house at exactly 7:45 AM on its way to Oslo.

When we answered the time question indirectly, we implied a reference to something that was commonly known. Grice has extended this notion of implying to something he called (with a self-concocted term, as he admits; Grice, 1981: 184–185) an *implicature* (see **Implicature**). Implicatures can be thought of as infringements on conversational cooperation, by going against one or the other of the conversational maxims. One such maxim is that of relation (or relevance: my answer must have some relevance to the question asked; see **Relevance Theory**). When we look for a relevant feature in an answer that *prima facie* seems to have little to do with what I was asking about, the implicature is of something behind the answer.

Grice's famous example is of the uncooperative college professor who, in reply to a request for a recommendation, writes that the student in question has always attended his lectures, and is a capable English speller. By not saying anything that is relevant (e.g., in a job application for an academic position), the professor implicitly indicates that the student is not a person he wants to recommend. So what at first looked like an uncooperative answer, in the end achieves the communicative needs of the situation by implicitly providing an answer that is useful to the requester.

Or consider the case of the person (related in Mey, 2001: 78–79) who is asked for an I.D. card on entering a discotheque and remarks to the doorman that she is the mother of four. Given that the drinking age at that point of time in this particular state (Louisiana) was 18, the fact of having four children more or less precludes the speaker's being under age for the purpose of drinking. But this is not said directly; the answer is a 'flout' of the maxim of relation (what does having children have to do with drinking?), but the implicature makes this a potentially good reply. In the actual case, however, the doorman refuses to recognize the implicature, and answers by another flouting of the maxim of relevance: "Yes, and I'm the Pope's granddad" – a truly absurd assertion given the ages of the then reigning pope (Paul VI in his later years) and of the doorman (at most 25). This new flout therefore implicated an answer in the spirit of: "You can tell me what you like but I cannot believe you at face value; show me an I.D. or just leave" (see **Maxims and Flouting**; refer also to an important study by Greenall, 2002).

The 'Garden Path' and 'Bestrangement'

A particular form of implying is often called the already mentioned 'garden path': an interlocutor is made to infer an implicature that is not really

there (but only exists in the speaker's mind), but then is intentionally suggested as valid in order to lead the conversational partner(s) astray. The motivation for creating such implicatures can be either political, as in the anecdote below (which I have called 'Adam in the Garden'; Mey, 2001: 258–259), or of a literary kind (as in the Cortázar example referred to earlier).

During the election campaign of 1970, incumbent Congressman Adam Clayton Powell, Jr., of the 18th Congressional District, was giving a press conference outside his opponent's headquarters at 135th Street and 7th Avenue in Harlem, New York City. A heckler interrupted him, asking him if he was going to be present at the antinarcotics parade to be held the next day, a Saturday, "like he'd promised." To which Powell replied that of course, nothing would keep him from attending. A moment later, the heckler interrupted again, wanting to make absolutely sure that the Congressman would be present at the parade. Powell, visibly irritated, reiterated his assurance, and went on with his speech. The heckler then intervened a third time, stating that "Well, Mr. Powell, sir, you ain't gonna be at that parade, 'cause there ain't gonna be one and we never spoke of one" (Source: *Harper's Magazine*, April 1971).

If we ask ourselves what was happening on that preelection Harlem Friday, we can say that the speech acts of asking questions (by the heckler) did not presuppose the existence of a real answer. The questions were disingenuous: the person asking them was well aware of their duplicity. The technique of the garden path leads the unsuspecting listener (or reader) into a verbal trap, which is then sprung at the crucial moment. Often (as in the case above), this is done with the intention of making a fool of the listener and (for political reasons, as in this case) humiliating him or her publicly. In order to better understand this technique, one could ask questions such as what speech acts can be identified in this interchange and how the Cooperative Principle applies here (if it does at all). Another interesting question would be how one could have saved Congressman Powell from going down the path, asking in particular where he took what first wrong step, and how he could have counter speech-acted to the heckler's remarks.

In other cases (mostly in a literary context) the use of the garden path is akin to the technique of making familiar things unfamiliar, a procedure called defamiliarization or *estrangement* (see **Literary Pragmatics**). The point here is to jolt the reader and obtain some kind of narrative shock effect; the effect is obtained by allowing the reader to make the normal inferences based on what we know about society,

language, and ourselves. When we enter a room, we expect there to be windows; anything that looks like a window will be seen and perceived as such. When we read about a couple taking a vacation, our inference is that of the normal, heterosexual couple. When Cortázar, in the story referred to above, suddenly breaks into our normal world by unveiling the true character of this couple, we are suddenly confronted with another view of our society, one in which the normal couple may be a same-sex one. The garden path teaches us something about the paths that are there, as well as about paths not taken by everybody.

Situated Speech and Pragmatic Acts

On the basis of the examples given, we conclude that any speech act, in order to be successfully executed, not only has to obey the conditions laid down by speech act theorists such as Searle and Grice, but in addition must be appropriately uttered, that is, it has to respect and conform with the situation in which it is executed.

A recent controversy erupting around the Danish army contingent stationed in Iraq was provoked by the fact that one of their translators balked at rendering Danish swear words verbatim into Arabic during prisoner interrogation at the Danish contingent's headquarters. Whereas the Danish interrogating officer was of the opinion that the Iraqi prisoners ought to be roughed up a bit by among other things, verbal intimidation, including threats and swear words, the native Syrian interpreter (who had spent most of his adult life in Denmark and hence was completely familiar with typical Danish swearing behavior) refused to go ahead and use words that, in his view, not only were offensive, but also would not work in the situation. He expressed as his considered opinion that an Iraqi would attribute the use of such swear terms, when translated literally into Arabic, as offensive verbal behavior, indexing an uneducated person. It would put the speaker far below the addressee, socially and interactionally, and preclude any cooperation. Hence the technique that the Danish interrogation officer wanted to employ was not appropriate to the situation, and an inappropriate act of interrogating would elicit no proper response. The interpreter, who clearly perceived the Danish and the Iraqi attitude as situationally incompatible sent in his letter of resignation 5 weeks prior to the expiration of his term, accompanied by an explanatory letter addressed to his commanding officer. This letter was then printed in the Danish press, causing a huge commotion; a public scandal erupted, resulting among

other things in the Danish interrogation officer being recalled from duty in Iraq.

As we saw in the case of the indirect speech acts, such acts receive their full potential usefulness from the situation in which they are properly uttered. What is lacking in verbal explicitation, is supplied by the implicit conditions of the situation. But conversely, the situation conditions the appropriate utterances in the sense that it enables certain utterances and excludes others, as we saw in the case of the bilingual Danish-Arabic interpreter.

Generalizing these observations, we may say that no speech act is complete, or even possible, without, and outside of, its proper situational conditions. A speech act, in order to be properly executed, has to be situated properly. This condition comprises not just the words spoken, but the presuppositions that are inherent in a situation, such as a nationally and culturally oriented understanding of proper linguistic behavior; a familiarity with conditions leading up to, as well as away from, a situated speech act; an understanding of the individual utterer's personal and social self-image; a correct interpretation of the accompanying body language and gestures; and so on and so forth. If we take all these aspects together, we arrive at the conclusion that there are no speech acts as such (except in the treatises and grammars written by linguists) and also, that every speech act, in order to be a valid act, must be rooted in a situation that supplies it with legitimacy (see **Pragmatic Presupposition; Intercultural Pragmatics and Communication**).

As we have seen, this legitimacy has not just to do with speaking, but more so, maybe even mostly, with the social and situational command that one has of the situation in which the words are spoken. Already Austin, in his *How to do things with words*, had had this insight (cf. the quotation above); for him, the primordial speech act was precisely a situated one. True, Austin interpreted this situation as one of strict societally defined custom (such as institutional surroundings in a court room, a lecture hall, or a church); my interpretation expands on this by saying that every situation belongs to some institution, whether officially constituted or not, and that every act of speaking is a situationally grounded and legitimated activity (see **Institutional Talk**). To characterize such an activity, I have coined the term 'pragmatic act' (see **Pragmatic Acts**). "Pragmatic acts are pragmatic because they base themselves on language as constrained by the situation, not as defined by syntactic rules or by semantic selections and conceptual restrictions. Pragmatic acts are situation-derived and situation-constrained; in the final analysis, they are

determined by the broader social context in which they happen, and they realize their goals in the conditions placed upon human action by that context" (Mey, 2001: 228).

The Pragmatic Turn

From the early 20th century on, the study of language had been defined, following Saussure, as the study of its system and structure. The methods for studying language were borrowed from the natural sciences; the rules that were assumed to govern the use of language were thought of as operating on the model of physical laws, being testable according to the prediction method: a hypothesis generates a statement about certain phenomena, and we can empirically ascertain whether or not the prediction holds. So, too, a rule in linguistics should correctly predict what happens in language, and it should be as general and simple as possible, while capturing all and only the facts.

This model of linguistic methodology (accepted by all those working in the structuralist tradition, from Bloomfield to Hjelmslev to Chomsky) was subsequently refined by the incorporation of mathematical and computational methods and techniques. Chomsky's main thesis, in particular, that a grammar of a language should be able to generate all the correct sentences of a language and none of the incorrect sentences, met with wide acclaim, and became the implicit code for much of linguistic work during the latter half of the last century.

Meanwhile, as we have seen, opposition to this mechanistic way of thinking about language arose from several quarters. Not only among the linguists, but mainly among the philosophers (Austin, Searle, and their followers) and anthropologists (Hymes, Hanks), among the sociologists and conversational analysts (Goffman, Sacks, Schegloff), the insufficiency of the standard linguistic method when it came to capture the full reality of human language use was keenly felt. Also among the literary theorists, following the rediscovery of the pioneering works of Soviet thinkers such as Bakhtin, Voloshinov, and others, the interest in the social aspects of language and its use in narration in particular became a prime factor in destabilizing the current linguistic paradigm, especially as embodied in the Saussurean distinction between *langue* and *parole* (see **Bakhtin, Mikhail Mikhailovich; Voloshinov, Valentin Nikolaevich**). In Western Europe, where the Russian scholars, for political reasons, had been rather poorly known, the surge of anti-establishment thinking of the 1960s and 1970s (spearheaded by a return to Marx) had a

great impact on what we now can see and name as the pragmatic turn in language studies (see **Marxist Theories of Language; Social Aspects of Pragmatics; Literary Pragmatics**).

In order to properly understand the import of this turn, let's go back to the case of speech acts, referred to above. There are basically two ways of looking at human speech activity: one is to consider the language used, the other is to look at the situation in which the language is used. Clearly, the two aspects should not be separated: there is no language use except in situations, and no situation is complete without the language that goes with it. However, in a linguistics-oriented approach we will always start out with the words, then try to "fit them to the world," as Searle used to say. The question is then: given these words, what can they do? If I say *Open the window, please*, what is the effect of this language use on the world (including the window in question, but also myself and my interlocutors, far and near)? In this approach, I start with the language and work my way to the outside, the world. The main focus in most cases is on the language used for ordering and the conditions that accompany this speech act.

Conversely, I may start out with a given situation: a window has to be closed. The question is: What language is appropriate, given the situation? I may say *Close the window, please* to somebody nearby; but I could also say, *Isn't it a bit cold in here?*, or any other indirect speech act that will do the job (sometimes even a grunt or a significant look will be sufficient). Rather than focusing uniquely on the words, pragmatics tries to capture the situation as a whole, and work its way to the inside, where the spoken words are found. Here, the use of language, such as a speech act, is an important part, but not the only one, of the situation.

In this, as in all use of language, the main protagonist is neither the language nor the situation, but the user and his or her situational conditions. The user decides on what language to use, but does this strictly in accordance with the situational context, as we saw above. Indeed, in many situations the use of a specific, canonical speech act is probably the user's last choice. One does not say *I hereby incite you to riot* to effectuate a speech act of inciting to riot – in fact, given a situation of inciting, almost any speech act will do, as Kurzon has remarked (1996). This line of thinking has led me to believe that the indirect speech act, as it is usually described, is not the exception but the normal case: all speech acts are situationally bound and conditioned, hence to a certain degree indirect in that they depend on the situation in which they are uttered.

In other words, a pragmatic approach to speech acting, and in general to language use, moves from the outside in: given this situation, what words will be appropriate for a particular act? In contrast, speech act theory, in its classical shape, works from the inside out (as does linguistics): given these words, how can I use them in a situation? This is basically the traditional semantic problem of the meaning of words; it is solved by trying to find a context in which the words will fit, rather than by starting out with the context and determining which words or expressions will fit a particular contextual slot. Curiously, it is this latter, textually based, prepragmatic approach to linguistics that was also the ideal of a structuralist like Hjelmslev: one starts from the entire text and arrives at the text's minimal constituent units through successive analytic operations; the problem was that in this kind of analysis, the user never was taken into account.

When we speak of a pragmatic turn, it is this kind of change of direction we have in mind. It is not just that some linguists turned to pragmatics, or even turned themselves into pragmaticists by fiat or "chosen affinity" (Goethe's expression). It is the method itself that has been turned on its head (or stood on its legs, if one prefers): rather than being a language-based operation, pragmatics advocates a user- and situation-based approach. It is also here that the relationship between semantics and pragmatics can be turned from an "unhappy marriage" if ever there was one (to borrow Georgia Green's expression, when she characterized the relationship between syntax and semantics; Green, 1989) into a healthy relation of mutual respect. Thus, the pragmatic turn in linguistics can be described as a shift from the paradigm of theoretical grammar (in particular, syntax) to the paradigm of the language user. The latter notion is of particular importance for defining pragmatics, since it brings a number of observations to the same practical denominator (see below; cf. Mey, 2001: 4).

It is also in this sense that we can define pragmatics as "studying the use of language in human communication as determined by the conditions of society" (Mey, 2001: 6). For, while it is true that communication in society chiefly is practiced by means of language, still, the language users, being social animals, can only use their language on society's premises. The social order controls and conditions communication in society; society controls and conditions people's access to the communicative means, in particular the linguistic ones. Given its focus on the human use of language and other communicative

means, the proper task of pragmatics is to study how those societal conditions allow and determine such a use.

The Difference that Makes a Difference

A final question needs to be answered: given that we do have this pragmatic turn, and admitting that it is the right direction to take in our study of the human use of language, a question still lingers in our minds, *viz.*: does it really mean that much which way we look at the relation between humans and their language, inside-out or outside-in? What I would like to show in this final section is that there is a difference, and that this difference indeed does “make a difference” (using Bateson’s formulation).

First off, there is the emphasis that the outside-in approach places on the social aspect of all language use. Placing the user in focus, as I advocate in the definition given above, reflects this primordial character of pragmatics as a societally based and societally conditioned study. This is not just to say that we look at social classes or groups, and then try to figure out what kind of (different) language and dialects they speak (the classical sociolinguistic approach, as practiced by, for example, William Labov and his school. In pragmatics, the concern is first of all to ‘read’ the user as a social *siglum*, a ‘sign’ to be decoded in accordance with societal parameters.

One of the first questions to ask then, is not what does this utterance mean? but how come this utterance could be produced at all? (Haberland and Mey, 1977, 2002) Asking the question in this way opens up an understanding of the speaker’s and hearer’s “affordances” (Mey, 2001: 220–221): what can a language user afford to say/hear/understand/execute as a speech act? Clearly, as already the original speech act theorists had seen, an order in the military or some other hierarchically organized body that is issued without proper authority is null and void. But even in more mundane situations (such as asking a simple question), one has always to think of what this question represents for the person who is asked to answer. Certain items may be tabooed in a particular culture; take for instance the proper name that is given a person in the Navajo community upon attaining adulthood, a name that is not to be divulged except to those with whom one has the greatest intimacy. Similarly, the old adage *De mortuis nil nisi bene* (‘Say only good things about the dead’) may reflect an age-old taboo: the dead may come back and take revenge when spoken about disrespectfully. The social norm, as expressed in what we now would call a superstitious belief, allows for certain types

of speech and forbids the use of others, depending on the situation.

The importance of this point of view in, for instance, a teaching situation is enormous. Getting to know the background from which one’s students speak is not only important in an inner city school with a majority of Black students (and often a sizable portion of White teachers), where the curriculum is geared towards White middle class values and White middle class ways of speaking and thinking are preferred (*see Classroom Talk; Class Language*). Pragmatics is also of help when trying to avoid language clashes, or even language wars, in which we construct linguistic and social differences as the barricades from which deadly battles are fought. In perhaps less serious cases, the educational future of whole generations is jeopardized because of the teachers’ lack of understanding of their pupils’ social and cultural background: in Botswana primary schools, students sit in the classroom and do “safe time” without learning anything useful, as Arthur (2001) has made clear; elsewhere, misunderstood language policies are imposed without regard to the students’ needs (as superbly demonstrated by Canagarajah in his discussion of the language situation in Jaffna, Northern Sri Lanka; Canagarajah, 2001).

In a broader framework, one could raise the question of whether pragmatics is useful in situations like those experienced on a daily basis in the developed countries of Western Europe, where immigrants from poorer parts of the world arrived *en masse* during the 1960s and 1970s and will continue to pose problems of acculturation for many generations to come. The problems can basically be reduced to this dilemma: should people from other cultures be politely asked (or even forced) to leave their cultural baggage behind and dress up in the hosts’ cultural garb, or should they be allowed (or maybe even forced) to set up their own cultural ghettos, where they can live and breathe the familiar air of their home surroundings?

The problem hinges on a proper (that is, pragmatic) interpretation of the term ‘culture’ and its epiphenomenal adjective, ‘intercultural.’ Such a view bases itself on a pragmatic and mainly contextual understanding of culture. On the one hand, culture, in order to flourish, has to have a cultivating environment, a context; pragmatics, on the other hand, in order to be true to its definition, has to respect the individual’s choice. As to the first point, no culture belongs exclusively to any individual or group of individuals; neither can culture be freely and noncontextually moved around. A culture presupposes a cultural environment, a growth context, just as the properly conditioned soil is necessary for a successful (agri)culture. But also,

pragmatics as defined above is a theory of human behavior (linguistic and otherwise), which explicitly depends on, and is conditioned by, the profile of the user. Hence we must inquire as to what in the actual circumstances is culturally feasible and pragmatically desirable for the individual as well as for the group.

A great deal of flexibility is required in order to avoid either of the two extremes: the culture-only view, where one blindly focuses on a particular culture and wishes for its perpetuation, no matter what, and the pragmatic-only view, which defines the uses of language simply from a (mostly utilitarian) user point of view: what is needed to guarantee the immigrants a not only culturally, but also economically viable existence?

Through research and practice, the field of intercultural pragmatics tries to build a bridge between the two extreme positions; it safeguards the culture as culture while attending to the needs of the users. Here, it should be borne in mind that cultures are not absolute or eternal values; even more important is the realization that humans are humans and have human needs that neither the cultural nor the pragmatic view should be allowed to abrogate. Among these needs belongs, first and foremost, the need to self-determine one's relationship to one's culture and to the culture of the host country. As pragmatic researchers, we should consequently steer a middle course between the extremes of pious romanticism and bone-hard realism, as I have indicated elsewhere (Mey, 2004) (*see Intercultural Pragmatics and Communication*).

Conclusion: 'Out of the Waste Basket'

From its humble beginnings as a place where one could deposit the unsolved (and perhaps unsolvable) problems that the classical parts of linguistic studies (such as syntax and semantics, perhaps even phonology) wanted to get rid of, at least temporarily, to the present state of pragmatics as a fully fledged representative of the linguistic disciplines, not much time has elapsed.

Forty odd years ago, the famed Israeli linguist Yehoshua Bar-Hillel (1971) coined the catchy phrase that figures at the head of this section; in his opinion, pragmatics served as a temporary stop for all the things that syntax and semantics could not deal with: a kind of linguistic waste basket. Now, not so many decades later, the waste basket has served its function – I am not saying it is quite empty yet, but we have managed to upgrade the basket to a more prominent position, and accorded it descriptive and explanatory status as a recognized field of language studies.

The relationship between pragmatics and the other linguistic disciplines, especially semantics and pragmatics, may still give rise to heated dispute (cf. what is said above; *see Pragmatics and Semantics; Phonetics and Pragmatics*), but nobody today would deny pragmatics its place in the sun. Moreover, pragmatic studies have diversified themselves into such various fields as second language education and educational settings in general, questions of gender-based language use and language discrimination (*see Gender and Language*), the intercultural dilemma of assimilation vs. ghettoization (*see Intercultural Pragmatics and Communication*), the struggle for linguistic rights and the fight against linguistic imperialism (*see Linguistic Rights; Pragmatics: Linguistic Imperialism; Linguistic Decolonization; Minority Languages: Oppression*), and so on. Even recent developments in the area originally known under the label of human–computer interaction have begun to recognize the impact of pragmatic thinking (*see Cognitive Technology; Adaptability in Human-Computer Interaction*).

What this shows is first that pragmatics is not a unified discipline in the sense that it acknowledges a unique method and focuses on only one object. Second, the diversity of the areas where pragmaticists are active is best captured if we consider pragmatics not to be an independent component of linguistics (on a line with, say, semantics or syntax) but rather as a perspective on the way we study language – a perspective that at the same time informs our study of human interaction in the direction outlined above. As the British pragmaticist Norman Fairclough has observed, the pragmatic perspective being a critical one, it examines and states “the conditions under which interactions of a particular type may occur” (Fairclough, 1995: 48) – interactions that include speech acting, conversational interaction, language use in institutional settings, the discourse of literature, the prescribed language use in schools and other official surroundings, the language of sexual oppression and counter-oppression or emancipation, the fight for linguistic rights, and so on and so forth. Fairclough continues: “such a statement cannot be made without reference to the distribution and exercise [of power] in the institution and ultimately, in the social formation,” that is, in society at large. (Fairclough, 1993: 48; Mey, 2001: 320–321). On the notion of perspective, see further Haberland and Mey (1977: 21), Verschueren (1999: 7), and Mey (2001: 9–11) (*see Power and Pragmatics; Critical Language Studies*).

Principles and Rules

L Mao, Miami University, Oxford, OH, USA

© 2006 Elsevier Ltd. All rights reserved.

The concept of ‘rule’ and ‘principle’ is perhaps as venerable as the study of language practices. The view that one particular variety of language is inherently more valuable contributes to the formation of prescriptive rules in relation to grammar, vocabulary, and pronunciation. The 18th century witnessed the need to standardize, to codify English, whose uniformity was promoted in the interest of the newly created union (Crowley, 1996) and whose imposition throughout the British Isles became part of what Leith (1997: 151) calls “internal colonization”. On the other hand, China at the turn of the 20th century experienced the need to break loose from the rules and conventions of classical Chinese as it tried to vernacularize its language as part of its modernization effort to create a new language of modernity and progress (Gunn, 1991).

In contemporary linguistics the term ‘rule’ assumes a new meaning, one that should not be confused with prescriptive rules. According to Noam Chomsky (1957), the rules of language are syntactic and generative, because language is both rule governed and predictable. Chomsky further distinguished the rules of grammar from principles of grammar – the latter do not generate sentences, but act as a set of tests that a sentence must pass to be part of a given language (1986).

However, meaning often defies both predictability and testability, especially when it becomes extralinguistic, and when well-formedness transcends syntax. Instead of focusing on rules of grammar, be they prescriptive or generative, language philosophers and pragmatists focus on “the total speech act in the total speech situation” (Austin, 1962: 149), on rules that either regulate (preexisting) language behavior or create or define new forms of language behavior (Searle, 1969), and on pragmatic principles that can account for the use of language as determined by societal conditions (Mey, 2001). For example, Grice (1975, 1989) developed the cooperative principle, whereby anyone who has a rational interest in participating in talk exchange is expected to be cooperative, to make his or her contribution as required. The cooperative principle, which for Grice is assumed to be in force all the time, and which has been faulted because it elides interpersonal, intercultural power dynamics, subsumes the conversational maxims of quantity, quality, relation, and manner (Grice, 1989: 26). What has to be underscored is that we comply with the maxims as much by

flouting them as by honoring them – hence we can mean more than or other than what we say.

Brown and Levinson (1987) turned their attention to politeness principles, proposing that there is a public-self image that we all want to claim and protect – one that consists of the want to be stroked (positive face) and the want to be left alone (negative face). These two competing wants and their concomitant claims for universality have spawned a large body of work on politeness pragmatics. Leech (1983) offered his own principle of politeness, which is predicated upon the notions of cost and benefit, and directness versus indirectness; he further offered a number of subprinciples to account for stylistic aspects of expression. And like Horn (1984), who tried to reduce Grice’s conversational maxims, Sperber and Wilson (1995) contended that what is only required for the hearer to work out the speaker’s intended message is the principle of relevance, because we humans turn our attention to what seems most relevant to us automatically.

While the formulation of pragmatic principles has greatly extended the scope of linguistics, pragmatic principles themselves do not equip language users with the means to reflect upon the conditions under which they use, or fail to use, language. Metapragmatic principles seek to promote metadiscursive awareness and to account for those underlying forces that, be they local or crosscultural, motivate or constitute particular pragmatic principles (Mey, 2001). This kind of self-reflectiveness becomes central to cultivating critical language awareness, to facilitating an emancipatory use of language (Fairclough, 1989), and to forever asking ourselves: “Whose language are we using?” (Mey, 1985).

Proxemics

M Danesi, University of Toronto, Toronto, Canada

© 2006 Elsevier Ltd. All rights reserved.

Introduction

An intrinsic feature of social contact rituals involves the maintenance of specific zones that people perceive as meaningful. The study of such zones now falls under the rubric of 'proxemics,' a word derived from the Latin *proximus* 'near' and the suffix *-emics*, in analogy with such terms as 'phonemics' and 'morphemics' in linguistics. The term thus betrays a connection to linguistic notions as the basis for studying and describing interpersonal zones, which involve knowing how close to stand to someone during social interaction on the basis of age, degree of familiarity, gender, etc.

Proxemics was founded by the American anthropologist Edward Twitchell Hall (1914–) in the late 1950s and early 1960s (1959, 1963a, 1963b) after his systematic study during World War II, when he served in the US Army in Europe and the Philippines, of the zones people maintain. Hall came to realize that failures in intercultural communication arose typically from unconsciously coded differences in the ways that members of different cultures perceived interpersonal distances and in the ways they acted within them. Hall developed proxemic methodology throughout the 1960s and 1970s (1959, 1963a, 1963b, 1964, 1966, 1968, 1974, 1976, 1983). Using American culture as his test case, he showed how it is possible to measure and assess critical interpersonal zones.

In 1963, Hall defined proxemics broadly as "the study of how man unconsciously structures micro-space – the distance between men in conduct of daily transactions, the organization of space in his houses and buildings, and ultimately the layout of his towns" (Hall, 1963b: 1003). A year later, he limited its purview somewhat to "the study of the ways in which man gains knowledge of the content of other men's minds through judgments of behavior patterns associated with varying degrees of proximity to them" (Hall, 1964: 41), which he restricted further a few years later to the study of "the interrelated observations and theories of man's use of space as a specialized elaboration of culture" (Hall, 1966: 1).

Hall's proposal to study the distances people maintain between each other has led to a large body of data on this aspect of social behavior. Most of the data shows that interpersonal zones are measurable with statistical accuracy, varying predictably and systematically according to age, gender, and other social variables (e.g., Segaud, 1973; Loof, 1976; Pinxten *et al.*, 1983; and Watson and Anderson, 1987). Today, proxemics is a robust area of research pursued by all kinds of social scientists (Mehrabian, 1969, 1972, 1976; Sundstrom and Altman, 1976; Canter, 1977; Moles and Rohmer, 1978; Harper *et al.*, 1978; Argyle, 1988; Lawrence and Low, 1990; Niemeir *et al.*, 1998). Hall did not explicitly use semiotic notions to study proxemic behavior, but his whole outlook and framework are, *de facto*, semiotic in nature. The inclusion of proxemics as a branch of nonverbal semiotics started with Eco (1968: 344–349) and Watson (1970, 1974).

The Proxemic Paradigm

The study of proxemic behavior consists of three general components (Hall, 1966; Watson, 1974): (1) spatial dimensions, (2) levels of interpretation of these dimensions, and (3) physical features of spaces. Each one consists of three subcomponents, called 'micro,' 'meso,' and 'macro.' 'Microspace' is the immediate physical environment constituting a sphere of privacy, 'mesospace' is the next zone that is within the person's reach but that falls outside the privacy sphere, and 'macrospace' refers to the larger social spheres, including settlements, cities, and beyond. The three levels of interpretation are called 'infra,' 'pre,' and 'micro.' The infra level is rooted in our 'biological past' (Hall, 1966: 95), involving our innate sense of territoriality as the guiding force in establishing boundaries. The pre level is rooted instead in inborn sensory (tactile, visual, etc.) perceptions of space that crystallize over time into culture-specific codings of space. Those are interpreted at a micro level. The three physical features are called 'fixed,' 'semi-fixed,' and 'dynamic.' Fixed features include such things as walls and territorial boundaries, semi-fixed features are mobile elements such as curtains and screens, and dynamic features are those such as vehicles that can vary in certain spaces.

Territoriality

Animals reside in territories that they have appropriated as their own, or in some negotiated arrangement with other animals, so that they can procure shelter, alimentation, and habitation. This applies to humans as well. But, unlike other species, humans also manifest a compulsion to ascribe social meanings to the territories in which they are located as groups.

Biologists define 'territoriality' as: (1) an innate survival mechanism that allows an animal to gain access to, and defend control of, critical resources such as food and nesting sites that are found in certain habitats, and (2) the instinctive need of an animal to procure a safe boundary around itself. The Austrian zoologist Konrad Lorenz (1903–1989) was among the first scientists to identify and document the patterns animals display in marking territoriality. Such patterns, he proposed, were an important part of an animal's repertory of survival strategies, as critical in evolutionary terms as its physiological endowments. Lorenz also suggested that human aggression and warfare were explainable as residual territoriality impulses – a controversial theory that gained widespread popularity through a best-selling book written in 1966 by Robert Ardrey, generating a heated debate in academia and society at large on the nature and

origin of human aggression. The notion of territoriality in human life continues to receive much support because of its intuitive appeal – intrusions into appropriated territories (e.g., into one's home, car, etc.) are indeed perceived typically as signals of aggression, in the same way that a cat, for example, would likely react aggressively to another cat intruding upon the boundaries it has claimed by urination.

The main implication to be derived from the work on territoriality is the fact that we all need to maintain a boundary around ourselves for our protection and sanity. Hall was among the first to see the relevant social implications of this, and thus to investigate the proxemic patterns people establish and maintain between each other when interacting. He noted that these could be measured very accurately, allowing for predictable statistical variation, and that the dimensions varied from culture to culture. In North American culture, Hall found that a distance of under six inches between two people was perceived as an 'intimate' distance; while a distance at from 1.5 to 4 feet was the minimum one perceived to be a safe distance. Intruding upon the limits set by this boundary causes considerable discomfort. For example, if a stranger were to talk at a distance of only several inches away from someone, he or she would be considered rude or even aggressive. If the 'safe' distance were breached by some acquaintance, on the other hand, it would be interpreted as a sexual advance.

Factors

Once the levels and features are determined, Hall posits eight factors as significant in proxemic behavior. These are:

1. Postural-sex identifiers (standing vs. sitting, male vs. female)
2. Sociofugal-sociopetal orientation factors (face-to-face, back-to-back)
3. Kinesthetic factors (distances of body parts, from reaching to contact)
4. Touching factors (from caressing and holding to no contact)
5. Visual factors (gazing, looking away, looking directly into the eyes)
6. Thermal factors (whether radiated heat is detected or not)
7. Olfaction factors (detection of odor or breath)
8. Vocal factors (loudness of voice, tone of voice).

As in linguistics, the idea of scientifically studying interpersonal zones involves two levels: (1) the actual physical description of the factors used *in situ*, known as 'proxetic' description (in analogy with 'phonetic'

description), and (2) the analysis of how these relate to each other structurally, known as 'proxemic' analysis (in analogy with 'phonemic' analysis). The relevant 'proxemes' are determined by comparing them and contrasting them to each other within the broader framework of an interaction.

Interpersonal Zones

Overall, Hall found that there are four main types of zones: 'intimate,' 'personal,' 'social,' and 'public.' Hall further subdivided these into 'far' and 'close' phases. For American culture, he found these to be as follows: (1) intimate distance (0 in.–18 in.), (2) personal distance (1.5 ft.–4 ft.), (3) social distance (4 ft.–12 ft.), and (4) public distance (12 ft. and beyond).

At intimate distance, all the senses are activated and the presence of the other person or persons is unmistakable. The close phase (0 in.–6 in.) is an emotionally charged zone reserved for love-making, comforting, and protecting; the far phase (6 in.–18 in.) is the zone in which family members and close friends interact. Touch is frequent at both phases of intimate distance. Personal distance is the minimum comfortable distance between non-touching individuals. In the close phase (1.5 ft.–2.5 ft.), one can grasp the other by extending the arms. The far phase (2.5 ft.–4 ft.) is defined as anywhere from one arm's length to the distance required for both individuals to touch hands. Beyond this distance the two must move to make contact (e.g., to shake hands). In essence, this zone constitutes a small protective space. Social distance is considered non-involving and non-threatening by most individuals. The close phase (4 ft.–7 ft.) is typical of impersonal transactions and casual social gatherings. Formal social discourse and transactions are characteristic of the far phase (7 ft.–12 ft.). This is the minimum distance at which one could go about one's business without seeming rude to others. Public distance is the distance at which one can take either evasive or defensive action if physically threatened. Hall noticed that people tend to keep at this distance from important public figures or from anyone participating at a public function. Discourse at this distance tends to be highly structured and formalized (lectures, speeches, etc.).

Conclusion

Semiotically, zones are signs that are governed by 'body codes' that also regulate bodily orientation. If someone is standing up at the front of an audience, he or she is perceived as more important than those sitting down. Speeches, lectures, classes, musical performances, etc. are oriented in this way. Officials,

managers, directors, etc. sit behind a desk to convey importance and superiority. Only their superiors can walk behind the desk to talk to them. To show 'friendliness,' the person behind the desk will have to come out and sit with his or her interlocutor in a different part of the room.

The study of such proxemic behavior has made it obvious that physical environments and the features within them are perceived as signifying structures. This is the reason why proxemics is now considered to be largely a branch or subfield of semiotics and is included in basic textbooks in the field (e.g., Nöth, 1990; Danesi and Perron, 1999).

Psycholinguistics: History

G Altmann, University of York, York, UK

© 2006 Elsevier Ltd. All rights reserved.

Our faculty for language has intrigued scholars for centuries. Yet most textbooks assume that psycholinguistics has its origins in the late 1950s and 1960s, and that nothing of note contributed to its evolution before then. In some respects this is true, in that it was only then that psycholinguistics began to proliferate as an identifiable discipline within the psychology literature. This proliferation was marked by the founding in 1962 of the *Journal of Verbal Learning and Verbal Behavior* (which subsequently, in 1985, became the *Journal of Memory and Language*). Why the original journal was so titled, and why its title presents us with a historical paradox, will become clearer as this review unfolds. The review's purpose is to consider how the present-day state of the art evolved. In so doing, it will touch briefly on ancient Greek philosophy, 19th century neuroscience, 20th century psycholinguistics, and beyond. It will consider approaches to the brain as practiced in both ancient Egypt and modern neuroscience. It will be necessarily selective, in order to make some sense of the historical developments that contributed to psycholinguistic science.

From the Ancient Egyptians to the Greek Philosophers

The earliest to write about language and the brain were the ancient Egyptians – the first to write about anything at all. A catalog of the effects of head injury

(and injuries lower down the body also) exists in what is now referred to as the Edwin Smith Surgical Papyrus, written about 1700 B.C. The writer (believed to have collected together information spanning perhaps another 1000 years before) referred there to what is presumed to be the first recorded case of aphasia – language breakdown following brain trauma. However, the Egyptians did not accord much significance to the brain, which unlike the other organs of the body, was discarded during mummification (it was scraped out through the nose). They believed instead that the heart was the seat of the soul and the repository for memory, a view largely shared by the Greek philosopher Aristotle (384–322 B.C.) – a somewhat surprising position to take given that he was a student at Plato's Academy and that Plato (427–347 B.C.) believed the brain to be the seat of intelligence.

Plato was possibly the earliest to write at length on language (where others may have spoken, but not written). Certainly, his writings were the most influential with respect to the philosophy of language and the question 'what does a word mean?' Plato, in his *Republic*, considered the meaning of words in his Allegory of the Cave (as well as in *Cratylus*). In this allegory, a group of prisoners have been chained all their lives within a cave. All they see are the shadows of objects cast upon a wall by the flames of a fire. They experience only those shadows (in much the same way that we can only experience the results of our sensory percepts), and their language similarly describes only those shadows. Plato noted that when using a word, the prisoners would take it to refer to the shadows before them, when in fact (according to Plato), they would refer not to objects in the shadow

world, but (unknown to the prisoners) to objects in the real world. Thus, for Plato (and a host of more contemporary philosophers, from Frege to Putnam), the true meaning of a word – its reference – is external to the person who, by using the word, is attributing meaning to it. But why should it matter what a word refers to?

The *psycholinguistic* endeavor is to uncover the mental processes that are implicated in the acquisition, production, and comprehension of language. Just as psychology is the study of the control of behavior, so psycholinguistics is the study of the control of linguistic behavior. A part of any psycholinguistic theory of mental process is an account of what constitutes the input to the mental process – that is, what information is operated upon by those processes. While Plato was of course correct that the form of the real-world object dictates the form of the sensory image presented to the allegorical prisoner, the mental processes involved in that prisoner's use of language can operate only on mental derivatives of that sensory image. There may be properties of the real-world object (such as color, texture, and density) that are not represented in their shadow-forms, and thus mental processes that might otherwise (outside the cave) develop sensitivity to those properties need never develop such sensitivities if constrained to living a life inside the cave. But while the shadows would not permit the distinction between, say, a tennis ball and an orange, the *contexts* in which the shadows were experienced, or their names heard, *would* distinguish between the two – mental sensitivities would develop, but they would not necessarily be grounded in the perceptual domain. These distinctions, between the actual world and our *experience* of the world, and between an object or word and the *context* in which that object or word might occur, led other philosophers, most notably Wittgenstein in his *Philosophical Investigations*, to propose that the meaning of a word is knowledge of its use in the language – that is, knowledge of the contexts in which it would be appropriate to utter that word, where such knowledge is shaped by experience. We return to this theme when we consider in more detail the more recent history (and possible future) of psycholinguistics.

The Earliest Empirical Studies

The pre-history of psycholinguistics (up until the 19th century) was dominated by philosophical conjecture. The term *dominated* is used loosely here, as there was no *systematic* and ongoing questioning of the relationship between mind and language, or indeed, brain and language – there was no *community* of researchers asking the questions. But modern-day

psycholinguistics is dominated not by philosophy (although it had its moments), but by experimental investigations that measure reaction times, monitor eye movements, record babies' babbles, and so on. Its pre-history lacks such experimentation. This is not to say that no experiments were performed. Certainly, there were isolated cases, generally of a kind that would not be tolerated in the modern age. Indeed, one of the most widely replicated studies (if one is to believe the historians) is a study that was carried out on at least three and possibly four independent occasions between the 7th Century B.C. and the 16th Century A.D. In each case, some number of babies were apparently brought up in isolation (except for carers who were either mute, or instructed not to speak), with the aim of the experiment being to discover what language, if any, the children would grow up speaking. The results varied. The Egyptian Pharaoh Psamtik (7th C.B.C.) was credited by Herodotus with discovering that they spoke Phrygian. The Roman emperor and German king Frederick II (1194–1250 A.D.) carried out a similar study, but all the infants died. King James IV (1473–1513 A.D.) is supposed to have performed a similar experiment on the island of InchKeith, although it is likely that this study never in fact took place (the fact that the children are reported to have emerged from their isolation speaking Hebrew is one reason to doubt the truth of the story). And finally, Akbar the Great (1542–1605), the grandfather of Shah Jahan who built the Taj Mahal, similarly failed to discover man's 'natural language' (although there is some suggestion that in this case, the infants acquired a form of signed language inherited, in part, from the infants' carers).

The 19th Century Emergence of the Cognitive Neuropsychology of Language

The first *systematic* studies of the relationship between language and brain were conducted in the 19th century. This is probably the earliest point in the history of psycholinguistics from when a *progression* of studies can be traced, with one author building a case on the basis of earlier studies coupled with newer data. The protagonists at this time were Gall, Boulliard, Aubertin, Broca, Wernicke, and Lichtheim, to name a few. None of them would be described as 'psycholinguists,' but to the extent that their work (like modern-day *cognitive neuroscientists*) informed accounts of the relationship between brain and language, they are no less a part of the history of psycholinguistics than are the linguists, philosophers, psychologists, and cognitive scientists who have influenced the field through their own, sometimes radically different, perspectives.

Franz Gall is perhaps better known for his work on phrenology, but he believed that language function was localized in the anterior parts of the brain. His student Jean Boulliard collected clinical evidence in support of Gall's theory, and in turn, Boulliard's student Ernest Aubertin did the same. It was at a meeting in April of 1861 that Aubertin made his beliefs plain: If a case of speech loss could be found that was not accompanied by a frontal lesion, he would give up his (and his intellectual forbearers') belief in the localization of language. In the audience was Paul Broca, after whom are named Broca's aphasia and, within the left frontal lobe, Broca's area. Broca was struck by Aubertin's empirical challenge, but at the same time realized that craniology (Gall's lasting influence on his students) could not provide the proof that was required to establish a link between language loss and cerebral localization – only anatomical inspection of the brain could do that. Coincidentally, within a few days he was presented with a patient suffering from speech loss who died a few days after that. Broca's postmortem analysis of this patient's brain (and the damage to what is now referred to as Broca's area), coupled with earlier observations made by Marc Dax (on right hemiplegia and its correlation with speech loss), but published at the same time, established the anatomical validity of the localization hypothesis. About 10 years later (in 1874), Carl Wernicke published his work on 'sensory aphasia' (deficits in the comprehension of language). This work was considerably enhanced by Wernicke's student Ludwig Lichtheim who, in 1885, produced a schematic (cf. a 'model') of how three interlinked centers in the brain are implicated in aphasia: Broca's (the 'center of auditory images'), Wernicke's (the 'center of motor images'), and a diffusely located 'concept center.' Lesions to each of these areas, or to the connections between them, produce different kinds of aphasias. Most interesting of all, his schematic enabled him to predict disorders that had not yet been described. This ability of a conceptual 'model' to make as yet untested predictions is a theme we shall return to.

The Early 20th Century Influence of Behaviorism

By the end of the 19th century, the study of language began to change, as did the study of psychology more generally. Interest in the psychology (as opposed to *philosophy*) of language shifted from being primarily (or even solely) concerned with its breakdown to being concerned also with its normal use. Wilhelm Wundt in *Die Sprache* (published in 1900) stressed the importance of mental states and the

relationship between utterances and those internal states. William James similarly (at least early on) saw the advantages of introducing mental states into theories of language use (see his 1890 *Principles of Psychology*, in which several contemporary issues in psycholinguistics are foreshadowed). But the early 20th century was a turbulent time for psycholinguistics (as it was for psychology): J. B. Watson argued that psychology should be concerned with behavior and behavioral observation, rather than with consciousness and introspection (the Wundtian approach). And whereas Wundt had argued that a psychology of language was as much about the mind as it was about language, behaviorists such as J. R. Kantor argued against the idea that language use implicated distinct mental states. For Kantor, the German mentalist tradition started by Wundt was simply wrong. Even William James turned away from Wundtian psychology. Thus, the behaviorist tradition took hold.

The late 19th and early 20th centuries were a time of great change in linguistics, too. The 19th century had seen the emergence of the Neogrammarians, a group that studied language *change*. They were interested in how the sounds of different languages were related, and how within a language, the sounds changed over time. They were less interested in what a language 'looked like' at a particular moment in time. This changed at the beginning of the 20th century when Ferdinand de Saussure brought *structure* into the study of language. He introduced the idea that every element of language could be understood through its relation to the other elements (he introduced *syntactic* distinctions that are still central to contemporary linguistics). In the 1930s, the Bloomfieldian school of linguistics was born, with the publication in 1933 of Leonard Bloomfield's *Language*. Bloomfield reduced the study of language structures to a laborious set of taxonomic procedures, starting with the smallest element of language – the *phoneme*. In doing so, Bloomfield firmly aligned the linguistics of the day with behaviorism. And just as behaviorism eschewed mental states in its study of psychology, so the Bloomfieldian tradition eschewed psychology in its study of language. The study of language was firmly caught between the proverbial rock and a hard place – between behaviorism on the one hand and taxonomy on the other. Mental states were, the argument went, irrelevant – whether with respect to psychological or linguistic inquiry.

The behaviorist tradition culminated (with respect to language) with B. F. Skinner's publication in 1957 of *Verbal Behavior*. Here, Skinner sought to apply behaviorist principles to verbal learning and verbal behavior, attempting to explain them in terms of conditioning theory. Verbal behavior (and *Verbal Behavior*) proved

to be the final battleground on which the classical behaviorists and the mentalists would clash.

The Mid-20th Century and the Chomskyan Influence

In 1959, Chomsky published a review of Skinner's *Verbal Behavior*. He argued that no amount of conditioned stimulus-response associations could explain the infinite productivity or systematicity of language. With Chomsky, out went Bloomfield, and in came mental structures, ripe for theoretical and empirical investigation. Chomsky reintroduced the mind, and specifically mental representation, into theories of language (although his beliefs did not amount to a theory of psychological process, but to an account of linguistic structure). So whereas Skinner ostensibly eschewed mental representations, Chomsky apparently proved that language was founded on precisely such representation. Some later commentators took the view that the Chomskyan revolution threw out the associationist baby with the behaviorist bathwater. Behaviorism was founded on associationism. Behaviorism was 'out,' and with it, associationism. Symbolic computation was 'in,' but with it, uncertainty over how the symbolic system was acquired. It was not until the mid-1980s that a new kind of revolution took place, in which the associationist baby, now grown up, was brought back into the fold. The intervening 20 years were typical teenage years – full of energy, punctuated by occasional false hopes that nonetheless proved essential to the maturation process.

Two years before his review of *Verbal Behavior*, Chomsky had published *Syntactic Structures*, a monograph devoted to exploring the notion of abstract grammatical rules as the basis for generating sentential structure. According to Blumenthal in his 1970 account of the history of psycholinguistics, Chomsky's departure from the Bloomfieldian school was too radical for an American publisher to want to publish a lengthy volume that Chomsky had written outlining the new approach, and only Mouton, a European publisher (and presumably more sympathetic to the tradition that Chomsky was advocating) would publish a shorter monograph based on an undergraduate lecture series he taught at MIT. In fact, this is not quite accurate (N. Chomsky, personal communication); Chomsky had indeed written a longer volume (subsequently published in 1975), and it is true that initial reactions to the manuscript were negative (but, according to Chomsky, not unreasonable), but *Syntactic Structures* was not a compromise brought about through Chomsky's search for a publisher; he had not, in fact, intended to publish it.

Instead, Cornelis van Schooneveld, a Dutch linguist and acquaintance of Chomsky's who was visiting MIT and happened to edit a series for Mouton, suggested that Chomsky write up his class notes and publish them. This he did, and modern linguistics was born. Psycholinguistics became caught up, almost immediately, in its wake.

Chomsky's influence on psycholinguistics cannot be overstated. He drew an important distinction between 'competence,' or the knowledge we have about a language, and 'performance,' the use of that language (a distinction that was reminiscent of Saussure's earlier distinction between *langue* and *parole*). Both, he claimed, arise through the workings of the human mind – a mind, which furthermore is innately enabled to learn the structures of human language (although not everyone agreed with the arguments for a language acquisition device akin to a mental organ – a concise summary of the counter-arguments was written by Bates and Goodman (1999)). It is perhaps surprising that against the backdrop of *Syntactic Structures* and Chomsky's *Review of Skinner's Verbal Behavior*, a new and influential journal dedicated to research into the psychology of language should nonetheless, in 1962, give itself a title (the *Journal of Verbal Learning and Verbal Behavior*) that firmly placed it in the behaviorist tradition.

From Linguistic Competence to Psychological Performance

Chomsky's theories of grammar were theories of competence, not performance. And yet, his work on *transformational grammar* initiated a considerable research effort in the early 1960s to validate the psychological status of syntactic processing (the construction of representations encoding the dependencies between the constituents of a sentence). Many of these studies attempted to show that perceptual complexity, as measured using a variety of different tasks, was related to linguistic complexity (the so-called Derivational Theory of Complexity). However, whereas the syntactic structures postulated by transformational grammar did have some psychological reality, the devices postulated for building those structures (e.g., the transformations that formed a part of the grammatical formalism) did not. It soon became apparent that the distinction between competence and performance was far more important than originally realized – the linguists' rules, which formed a theory of competence, did not make a theory of psychological process.

Subsequently, the emphasis shifted toward examination of the psychological, not linguistic,

mechanisms by which syntactic dependencies are determined (a process referred to as *parsing*). In a seminal paper published in 1970, Thomas Bever pointed out that in cases of ambiguity, when more than one structure (i.e., dependency relation) might be permissible, there appear to be consistent preferences for one interpretation rather than another. This consistency appeared to hold not only across different examples of the same kind of ambiguity, but across different people, too. Thus, despite the grammaticality of *'the horse raced past the barn fell'* (cf. *'the car driven past the garage crashed'*), the preference to interpret *'raced'* as a main verb (instead of as a past participle equivalent to *'driven'*) is so overwhelming that the sentence is perceived as ungrammatical (and the preference is then said to induce a 'garden path' effect). Evidently, grammaticality and processability are distinct mental phenomena.

On the Influence of the Digital Computer

The 1970s saw enormous growth in psycholinguistics. Advances were made across a wide range of phenomena, including the identification of both printed and spoken words, the reading process, sentence comprehension (with much of the emphasis on the resolution of ambiguities of the 'garden path' kind), and the mental representation of texts. Whether there was a 'spurt' in the number of publications is contentious, because although there undeniably was such a spurt, the whole of psychology experienced the same rapid growth. It would be wrong, however, to attribute all this advancement to the influence of Chomsky. The demise of behaviorism played a part (and certainly Chomsky played a part in that demise), but so did the advent in the 1950s of the digital computer. The 'mind-as-computer' metaphor had a subtle but pervasive influence on both psycholinguistics and the study of *cognition* generally. Computer programs worked by breaking down complex behaviors into sequences of simpler, more manageable (and hence more understandable) behaviors. They relied on *symbol manipulation* and the control of *information flow*. They distinguished between different levels of explanatory abstraction (the high-level programming language, the assembly code, and the flow of electrical currents around the hardware). And perhaps most important of all to the empirical psychologist, they enabled novel predictions to be made that might not otherwise have been foreseen had the 'model' not been implemented in full; complex interactions among the components of a program were not easy to foresee.

The influences of the digital computing revolution were felt in different ways. Some were direct, with

researchers building computer simulations of mental behavior (in the growing field of *Artificial Intelligence*, several language 'understanding' programs were written, some of which are still relevant 35 years later – e.g., Terry Winograd's SHRDLU program written in 1968–1970). Other influences were indirect, coming to psycholinguistics via philosophy. One such example was Jerry Fodor's Modularity of Mind hypothesis (from 1983). One simplified interpretation of this hypothesis (it was interpreted in different ways by different researchers) was that there are two alternative ways of theorizing about the mind: one is to assume it is incredibly complex and that multiple sources of information interact in multiple ways, and the other is to assume that it can be broken down into a number of modules, each of which performs some particular function and is 'blind' to the workings of the other modules (perhaps taking as input the output of one or more of those other modules). Fodor argued that certain aspects of cognition were modular (the input systems), and certain others were not (central processes). This hypothesis had considerable influence in psycholinguistics, and for a time (the mid-1980s to early 1990s), hypotheses were evaluated according to whether they were modular or not. There seemed little agreement, however, on where one drew the boundaries (for example, was spoken language recognition a part of an input system? If it was, how could 'higher-level' knowledge of the context in which the language was being interpreted influence the modular and encapsulated recognition process? – Some argued it could not, while others argued it could). It was about this time, in seeming opposition to the trend toward *symbolic computation*, that a new computationally motivated approach to cognition emerged in the mid 1980s, apparently eschewing symbolic computation *and* modularity.

The Late 20th Century Emergence of Connectionism: Statistical Approaches to Language

In 1986, David Rumelhart and Jay McClelland published *Parallel Distributed Processing*. This edited volume described a range of *connectionist*, or *neural network*, models of learning and cognition, and marked a 'coming of age' for connectionism. It was, for many researchers in psycholinguistics, their first introduction to a wide range of research in this emerging field. Of particular interest were the facts that 'knowledge' in connectionist networks is encoded as patterns of connectivity distributed across the neural-like units, and 'processing' is manifest as spreading patterns of activation. These networks can learn complex associative relations largely on the basis of

simple associative learning principles (based primarily on work published in 1949 by Donald Hebb, a student of Lashley's). Various algorithms exist to set the 'strengths' of the connections between the units automatically, so that a given input pattern of activation across some set of units will spread through the network and yield a desired output pattern across some other set of units. Indeed, multiple input-output pairings can be learned by the same network. Importantly, and in contrast to the ideals of the behaviorist traditions, neural networks can develop internal representations.

Several connectionist models had profound effects on developments in psycholinguistics. TRACE, for example, developed by McClelland and Jeff Elman in the 1980s, was a model of spoken word recognition that formed the focus of empirical research for a good 20 years after its inception. But TRACE did not learn anything – it was hardwired. An extremely influential model that *did* learn by itself was described by Elman (1990), who showed how a particular kind of network could learn the dependencies that constrain the sequential ordering of elements (e.g., phonemes or words) through time. In effect, it learned which kinds of word could follow which other kinds of word (hence, it was a *statistical model*, because it encoded the statistics of the language it was trained upon). Interestingly, it developed internal representations that appeared to resemble grammatical knowledge; words that occurred in similar sentential contexts came to evoke similar internal representations (that is, internal patterns of activity when the word was presented to the network) – and because words of the same grammatical category tend to occur in the same sentential contexts, different 'clusters' of words emerged, with each cluster representing a different category of word.

Not surprisingly, the entire connectionist enterprise came under intense critical scrutiny from the linguistics and philosophy communities, not least because it appeared to reduce language to a system of statistical patterns, was fundamentally associationist, nonmodular, and eschewed the explicit manipulation of symbolic structures (because the internal representations that emerged as a result of the learning process were not symbolic in the traditional sense). Within the context of the symbolic-connectionist debate there developed what became perhaps one of the longest surviving disputes in contemporary psycholinguistics; between those that believe that word formation (e.g., the formation of 'walked' from 'walk,' 'ran' from 'run,' and 'went' from 'go') is driven by knowledge of *rules* and *exceptions* to those rules, and those who believe it is driven by *statistical regularity* (which can apparently capture, in the right model, both the

regularly and irregularly formed words). The debate shows little sign of abating, even 20 years later.

Critics notwithstanding, statistical approaches to language (both with respect to its structure and its mental processing) are becoming more prevalent, with application to issues as diverse as the 'discovery' of words through the segmentation of the speech input, the emergence of grammatical categories, and even the emergence of meaning as a consequence of statistical dependencies between a word and its context (cf. Wittgenstein's views on the meaning of words). Empirically also, the statistical approach has led to investigation of issues ranging from infants' abilities to segment speech and to induce grammar-like rules to adult sentence processing. The reason that such approaches have proved so appealing is that statistics are agnostic as to the nature of the real-world objects over which the statistics are calculated – thus, the fundamentally same algorithm can be applied to sequences of phonemes, words, or sentences. Their implementation within a neural network is similarly agnostic – the same network and the same algorithms that enable that network to induce the appropriate statistics can be applied to many different domains. Connectionism opened up experience-based learning to a range of psychological domains, not just the linguistic domains. And experience-based learning was attractive not least because it required fewer assumptions about the existence of innately specified domain-specific faculties (and in a multi-authored volume published in 1996, Jeff Elman teamed up with a variety of developmental psychologists to argue that connectionism was attractive precisely because it enabled a new perspective on how innate constraints on learning and neural structure might be an important component of human language acquisition (Elman, 1996)).

Neural networks can be criticized for being (among other things) too unconstrained – they can, in principle, do more than might be humanly possible – but the opposite criticism, that they are too small and do not necessarily 'scale up' is another criticism that is often heard. Neural networks as currently implemented are just the 'medium' on which are offered up the statistics. To misuse a common adage, the proof will be in the pudding, not in the plate that serves it up. There is little doubt, from the historical perspective, that although the emergence of connectionism has offered a powerful theoretical tool, its emergence has also polarized sections of the psycholinguistic community, between 'connectionists' on the one hand, and 'symbolists' on the other. This polarization is not unique to psycholinguistics, however, but pervades the study of cognition more broadly. And as if to further muddy the theoretical waters, the beginning

of the 21st century has seen renewed interest in yet another (no less controversial) paradigm – one that grounds language (and cognition) in action.

The Early 21st Century and the Grounding of Language in Action and the Brain

Traditional theories in cognition suppose that the job of the perceptual system is to deliver to the cognitive system a representation of the external world. The job of the cognitive system is then to reconstruct, mentally, that external world. This reconstruction subsequently forms the basis for ‘commands’ sent to, for example, the motor system. Cognition thus mediates between perception and action. An alternative approach, termed ‘embodied cognition,’ is that cognition and action are encoded within the same representational medium. Cognition is thus rooted in the same motoric and sensory representations that support interaction with the external world. Or, put another way, cognition is grounded in the same neural substrates that support sensory-motoric interaction with the external world. One consequence of this view is that language, a component of cognition, should, like the other components of cognition, be studied in the context of (i) the interactions it causes between the hearer and the world, and (ii) the neural substrates that support those interactions. Coincidentally, the 1990s saw a boom in research into the neural substrate of language, in part due to the increased availability of neuroimaging technologies (predominantly *PET* and *fMRI*, with *EEG* and more recently *MEG* also proving influential). It also saw increased research into the relationship between language and action. Taken together, these two streams of research provided increasing evidence for embodied cognition.

With respect to imaging, a variety of studies demonstrated what Lichtheim had alluded to a century earlier – that concepts are not represented in some discrete location within the brain, but are distributed across different regions. For example, words whose meanings implicate tool use (e.g., ‘hammer’) activate regions of the brain responsible for controlling motoric action (during the use of the tool) and other regions involved in the recognition of object form (during perception of the tool). Color words (e.g., ‘yellow’) and words referring to non-manipulable artefacts (e.g., ‘house’) do not activate motoric areas to the same extent, but they do activate regions close to those implicated in form perception and, for color words, color perception. Importantly, there is no single region that is primarily active; rather, words and concepts activate complex patterns of activity that are distributed and overlapping

within different parts of the brain that are known to have (other) motoric and sensory functions. The meanings of (at least some) words do appear, then, to be grounded in those neural substrates that support sensory-motoric interaction.

About the same time that increased attention was focusing on neuroimaging, new techniques for studying language and its effects on *action* were also being developed. One of these involved the monitoring of eye movements as participants listened to commands to manipulate objects in front of them, or as they listened to descriptions of events that might unfold within the scene before them (one can view language-mediated eye movements as central to the relationship between language and action, because eye movements signal overt shifts in attention, and because attention to something necessarily precedes (deliberate) action upon it). It was found that eye movements were closely synchronized with processes implicated in both spoken word recognition and sentence processing, and that much could be gleaned about what kinds of information were recruited at what point during a word or sentence in order to interpret the unfolding language with respect to the scene in front of the participant (it is not without some irony that in L. N. Fowler’s famous Phrenology bust, from about 1865, the faculty for language is located just below the left eye). Another technique involved measuring motoric responses to different kinds of linguistic stimuli – for example, words or sentences referring to movements toward or away from the body were found to interfere with responses in a judgment task (e.g., ‘does this sentence make sense?’) that involved moving a finger toward or away from a response button. A range of studies, some involving TMS (Transcranial Magnetic Stimulation – a method for either temporarily stimulating or suppressing a part of the brain, such as parts of motor cortex) have confirmed this motoric component to language comprehension.

It is noteworthy, with respect to the embodiment approach to cognition, that some of its basic tenets have been around since the earliest days of (contemporary) psycholinguistics. Winograd’s SHRDLU program, for example, viewed the meaning of a word such as ‘place’ or ‘lift’ as that part of the program that caused placing or lifting – language comprehension within that program was grounded in sensory-motoric representation – and as such, SHRDLU followed in the Wittgensteinian tradition of treating meaning as use. Similarly, it is noteworthy that although most of the neuroimaging of language has been carried out independently of theories of embodied cognition, much of the work converges on the same theme – that aspects of language are represented in the same

representational substrates that control our sensory-motoric interactions with the external world.

Epilogue

And that, broadly speaking, is where the field is now. In the space available, it is impossible to document all the trends that have influenced contemporary psycholinguistics, and which have influenced not just what kinds of language behavior we study (e.g., language breakdown, normal language use, ambiguity resolution, and so on), but also how we study those behaviors (through studying aphasia, neuroimaging, language-mediated eye movements, and so on). And we have still to see the full influences of connectionism, statistical learning, embodied cognition, and the neuroscience of language. What we can be sure of is that the boundaries between the study of language and the study of other aspects of cognition are wearing thinner (the eye movement research mentioned above is at the interface of language and vision, for example). No doubt there are already developments in 'neighboring' fields of study (e.g., the computational sciences and non-cognitive neurosciences) that will also have an impact, but have yet to emerge as quantifiable influences on psycholinguistics. For example, researchers are already using computational techniques coupled with detailed neuroanatomical research on the neural structure of the brain to attempt to understand the kinds of 'computation' that distinct parts of the brain may be capable of. Such research promises greater understanding of the brain's ability to learn, represent, and deploy language. And although the history of psycholinguistics is relevant to understanding where the field is today, perhaps of greater interest is where the field will be tomorrow.

Acknowledgments

This article is a substantially expanded version of a short, 1500-word section on the history of psycholinguistics that appeared as part of a broader review of issues in psycholinguistics (Altmann, 2001). The reader is referred to this paper for in-depth review of (some of) the topics that constitute the field of psycholinguistics. The author would like to thank the publishers of this article for donating his fee to the charity Médecins sans Frontières, and Silvia Gennari for advice on topics ranging from Plato to neuroimaging.

Emergence of Psycholinguistics in the Late 1950s and 1960s from the Chomskyan Revolution

Although the study of language has been part of psychology from its earliest years, including for example in the work of Wilhelm Wundt, the father of psychology, a distinct field of psycholinguistics emerged in the late 1950s largely in response to the impact of Chomsky. In the preceding decades, notably in the United States, psychology had been dominated by the behaviorist approach of researchers such as B. F. Skinner. They treated language as a form of verbal behavior, which, like all other behavior, they believed was governed by simple stimulus–response associations. Chomsky demonstrated the shortcomings of the behaviorist approach in explaining the productivity of language and its complexity, and his work, notably *Syntactic structures* (1957), provided a major impetus for a new kind of psychological investigation of language. This was driven by an interest in the mental representation of language in general and syntactic structures in particular (see **Psycholinguistics: History**).

Psychology since the demise of behaviorism has again been concerned with understanding the way that people accomplish various information-processing tasks. In the field of psycholinguistics this means a concern with the cognitive processes by which a string of sounds in an utterance, or marks on a page, are processed to identify individual words and sentences, and how this emerging structure becomes mentally represented as a meaningful concept. The goal of this process is to derive models that account for how people achieve this so rapidly and successfully, given what we know about the general limitations of human cognitive processing. To oversimplify: the psychologist is concerned with **how** the linguistic units are processed and represented; the linguist is concerned with the description of the structures that emerge from any such processes.

Research Topics in the Early Years of Psycholinguistics

In its early years psycholinguistics reflected the concerns of linguistics and the central role of syntax. Psychologists such as Miller and Isard (1963) showed that the syntax influences the way people interpret sentences, and even how many words people can

remember from a string of words that make no sense. More words are remembered from a ‘sentence’ like ‘Accidents carry honey between the house’ than from strings with no syntactic structure such as ‘On trains hive elephants the simplify.’ The focus on syntax and its importance in language processing led many psycholinguists to try to test the psychological reality of Chomsky’s theory of generative grammar. Experiments were designed to explore the notion that when people process sentences, what they are doing is retrieving the deep syntactic structure as described in Chomsky’s transformational grammar. So initially, a number of studies seemed to show that the relative ease or difficulty with which a reader or listener could process a given sentence was directly related to its syntactic complexity. Chomsky’s kernel sentences, equivalent to active affirmative declarative sentences, were recalled most easily and processed most quickly, while sentences including one or more transformations such as negative or passive forms were more difficult to process. These kinds of study led to the so-called derivational theory of complexity. This was superseded as it became clear that the results of many of the studies that apparently provided support for this purely syntactic view of how people process sentences could also be accounted for by the influence of semantic factors. Although sentence processing remains one of the most significant topics in psycholinguistics, the range of language phenomena that are studied has broadened considerably since the early 1960s. The assumption that the role of psycholinguistics is to demonstrate the psychological validity of any particular syntactic theory has also been overtaken.

Models of Sentence Comprehension

Many of the models of sentence comprehension that have been developed in psycholinguistics try to elucidate the cognitive processes that are involved when a reader or listener interprets a sentence. There is considerable experimental evidence that sentence comprehension is incremental, that is, that an interpretation is built up on a moment-by-moment basis from the incoming linguistic information. The evidence for this incremental processing is particularly striking in the way listeners recognize spoken words (see below), which are often identified before all the acoustic information has been heard.

Even in written language processing we have clear signs of the incremental nature of linguistic processing. This is illustrated by the difficulties most readers have with sentences like the following: ‘The horse raced past the barn fell’ (Bever, 1970). This is known

as a garden path sentence, because nearly all readers interpret this **while** they are reading, with ‘raced’ as an active verb and so expect the sentence to end after ‘barn.’ They do not realize that the sentence could have an equivalent interpretation to ‘The horse that raced past the barn, fell.’ The incremental way that sentences seem to be interpreted by readers or listeners is a major source of potential ambiguities of interpretation. Many sentences in a language have potentially more than one interpretation as they are processed, yet the reader or listener is usually not aware of any problem in arriving at one clear interpretation of a sentence.

The cognitive architecture that underpins such an achievement has been a source of much debate in psycholinguistics. Some researchers have held that in the frequent cases where more than one analysis of a sentence is possible, the reader or listener computes all possible analyses in parallel. The difficulty of garden path sentences has led others to propose serial models, where it is assumed that a single analysis is computed and corrected later if this is needed. Models have been proposed to account for the empirical evidence on sentence-processing difficulties. These often involve various versions of parallel analyses, where candidate analyses are only active for a brief period of time or are ranked according to frequency in the language or plausibility with the context. One of the most influential of these accounts is the constraint-based model of MacDonald *et al.* (1994). The weightings attached to each candidate analysis are based on the frequency of a syntactic structure in the language, the plausibility of the words in the sentence to their assigned syntactic roles, etc. So this model is an example of an interactive model where many different sorts of information, syntactic, semantic, pragmatic, contextual, and frequency, can all play simultaneous roles by activating alternative interpretations of the incoming linguistic information. In models of this type, semantic factors can override syntactic processing biases. This model is attractive to psychologists for a number of reasons. It is amenable to modeling by connectionist approaches and it avoids the problem of having to base cognitive processes on syntactic rules, which for psychologists appear to change arbitrarily with changes in linguistic theories.

In contrast, one of the other most influential models of sentence processing is the garden path model (Frazier, 1979). This uses only syntactic principles in its initial stage. An analysis is computed based on two syntactic preferences, the most important being the principle of minimal attachment, the other being the principle of late closure. The first principle means that the parsing of the sentence that produces the simplest parse tree, with fewest nodes, takes

precedence. So a sentence like ‘Mary watched the man with the binoculars’ is usually interpreted to mean that Mary (not the man) was using binoculars. According to Frazier’s interpretation of phrase structure rules, this interpretation involves one node fewer than the alternative and so demonstrates the principle of minimal attachment in action. This principle takes precedence over the principle of late closure. This is the preference to attach incoming materials to the current phrase or clause. This latter principle is used to explain the preference for interpreting sentences like ‘John said he will leave this morning’ to mean that the phrase ‘this morning’ relates to the verb ‘leave,’ not the verb ‘said.’

As part of the ongoing debate about the adequacy of different models of the parsing process there has been an active discussion in the experimental literature over several years about the extent to which semantic factors can override or guide the analysis of syntactic structure. This has been explored in several studies focusing on the ease or difficulty with which sentences containing reduced relative clauses can be processed. Several studies have tested how people interpret sets of sentences like the following:

- (1a) The defendant examined by the lawyer turned out to be unreliable.
- (1b) The defendant that was examined by the lawyer turned out to be unreliable.
- (2a) The evidence examined by the lawyer turned out to be unreliable.
- (2b) The evidence that was examined by the lawyer turned out to be unreliable.

Sentences like (1a), which contain a reduced relative clause, are more difficult to process than their equivalent full relative clause (1b). Readers initially treat ‘examined’ as a main verb whose subject is ‘the defendant.’ They then have to reanalyze this garden path when they reach the phrase ‘by the lawyer.’ The argument is the extent to which structurally similar sentences (e.g., [2a]) cause readers to have equivalent processing problems. This is what might be expected from a purely syntactic view of parsing. In contrast, in an interactive constraint-based model, the semantic implausibility of interpreting an inanimate noun such as ‘evidence’ as the subject of the verb ‘examined’ should protect the reader from the need to reanalyze an initial incorrect syntactic structure.

Trueswell *et al.* (1994) seemed to show just such a pattern. This was considered powerful evidence in support of interactive constraint-based models of sentence processing. More recently, Clifton *et al.* (2003) have challenged the evidence that semantic factors override syntactic processing in the initial stages of parsing. They used more sophisticated techniques for

monitoring and analyzing eye movements to determine the processing difficulties experienced by readers. They found that reduced relative clauses caused disruption to processing, irrespective of the semantic plausibility of the relationship between the apparent subject and main verb. Semantic factors, however, influenced how quickly the readers recovered from their wrong analysis of the syntax of the sentence. Clifton *et al.* (2003) stressed that the key thing for psycholinguistic models of sentence processing is not whether the data on processing reduced relative clauses support garden path or constraint-based models. They claim that the important goal is to develop parsing models that deal both with the task of creating structure and evaluating the structure that is created.

Although there have been numerous studies of sentence processing conducted by psycholinguists over the decades, the vast majority of these have focused on how readers interpret written sentences. A few studies have tackled the issue of how listeners use the cues in spoken language during parsing. Minimal attachment strategy can be shown to be overcome by the prosodic cues in real spoken sentences. Similarly, the principle of late closure, which can cause syntactic ambiguities in written sentences, can be less problematical in spoken materials because of clear prosodic cues to the intended interpretation. Even the apparent errors in spoken sentences, such as the disfluency ‘uh,’ can have an impact during the parsing process. Bailey and Ferreira (2003) presented sets of sentences to listeners such as the following:

- (3a) Sandra bumped into the busboy and the uh uh waiter told her to be careful.
- (3b) Sandra bumped into the busboy and the waiter uh uh told her to be careful.

These sentences are ambiguous up to the point when the listeners hear ‘told.’ ‘Sandra’ could have bumped into ‘the busboy’ or ‘the busboy and the waiter.’ Yet the listeners who heard the materials most often interpreted sentences like (3a) to mean that ‘the waiter’ was the subject of a new clause, i.e., that it was the subject of the verb ‘told.’ This shows that disfluencies can systematically influence the way listeners parse incoming sentences. The same effect was observed when the interruption was not a disfluency but an environmental sound such as a telephone ringing.

Speech Production and Speech Errors

These studies represent a welcome aspect of the broadening of the psycholinguistic research agenda to include more consideration to the production and comprehension of spoken as well as written

language. The study of speech disfluencies is one part of this. Speech disfluencies encompass a range of phenomena, including pauses in speech such as silences, filled pauses, and fillers such as ‘uh’ and ‘um,’ as well as speech errors such as slips of the tongue, spoonerisms, and malapropisms. When we speak we aim to produce a grammatically well-formed utterance with no noticeable hesitations. Yet this ideal delivery cannot always be achieved. It is estimated that around 5% of words in speech are disfluent in some way. Yet these disfluencies are not random in their patterns of occurrence. Even the similar-sounding disfluencies ‘uh’ and ‘um’ have been shown to have systematic contexts of use. Speakers use ‘uh’ before a short delay in their speech production but use ‘um’ before a more significant delay. Speakers seem to become disfluent because they are experiencing some kind of problem in planning and producing their utterance. Speakers have been found to pause more before unpredictable words, suggesting they might be experiencing word-finding difficulties. Speakers also pause more at the start of an intonation unit, which suggests that pausing is related to the speech-planning process.

Speech errors have also been studied by psycholinguists, who have classified them according to the assumed units of processing and types of mechanism involved in their production. For example, speech errors can relate to the phonemic features of the word, the syllabic structure, or the phrase or sentence being produced. This is illustrated in one of the famous errors reportedly produced by Dr Spooner in the 19th century when rebuking one of his students: ‘you have tasted the whole worm’ when he presumably intended to say ‘you have wasted the whole term.’ Here the initial phonemes are swapped but the rest of the morphemic and syntactic structure of the target utterance is preserved. Errors of this type became known as ‘spoonerisms’ as a result.

The kinds of error that occur can tell us a good deal about how speech is produced. Speech errors are very varied. They can reflect many different linguistic levels. Errors can involve the sounds of the words involved, for example saying ‘the lust list’ for ‘the lush list.’ They can relate to the intended words in a phrase, ‘the pin of a head’ being said in place of ‘the head of a pin.’ Errors may also focus on the semantic relations of the intended words, so a speaker may produce ‘I like berries with my fruit’ rather than ‘I like berries with my cereal,’ among many other forms of errors.

Some types of errors, however, do not occur and these patterns of occurrence and nonoccurrence have been used to help understand the speech production process. Content and function words are not

substituted for one another and indeed substitute words are usually the same part of speech as the intended target word. When the wrong sound is produced, however, the substituted phoneme seems to have no grammatical relation with the intended target sound. The spacing between the errors is also informative for models of production. Errors of word substitution usually involve words that are a phrase apart. Yet sound errors seem to relate neighboring words. This sort of evidence has been used by several researchers to develop general models of the speech production process.

Speech Recognition

Psycholinguists have also been concerned with exploring the processes involved in speech perception. Jusczyk and Luce (2002) summarized over 50 years of research on this topic. They described key research issues in the domain as understanding invariance, constancy, and perceptual units. In speech there are no invariant acoustic features that map directly to corresponding phonetic segments. The acoustic properties of sounds vary widely depending on the surrounding linguistic context. To make matters even more complex for the listener, there is also wide variability in the way phonetic segments are produced by different speakers depending on age, sex, and individual speaker characteristics. It is not even easy to determine what are the basic perceptual units that listeners use to recognize speech. Some research studies seem to suggest the phoneme as the basic building block of perception while others show advantages of the syllable over the phoneme. Conversational speech is therefore a very variable signal that does not even provide clear cues to boundaries between words. Yet understanding words in speech is an effortless and successful process for listeners with normal hearing. How is it done?

One of the key research challenges for psycholinguists was therefore to produce models of spoken word recognition. One of the most influential models is the Cohort Model (Marslen-Wilson and Welsh, 1978; Marslen-Wilson, 1989). In this account, when a listener hears an initial sound, all the words known to start with that sound become activated. This cohort of candidate words is gradually whittled down to a single word, as more acoustic information is processed and candidate words are eliminated. An important feature of the model is the uniqueness point. This occurs when the listener has heard enough acoustic information to reduce the cohort to a single candidate, i.e., there are no other words known to the listener with that particular sequence of phonemes. Syntactic and semantic context from the surrounding

discourse can also play a role in rejecting potential candidate words. In later versions of the model, this can only occur after the uniqueness point, though in earlier versions, context could also be used to eliminate possible words before the uniqueness point. The recognition point occurs when a single item remains in the cohort. This may be before the end of a word.

One of the strengths of the model is the way it can account for the speed with which spoken word recognition often occurs, often occurring before the word offset. In later versions of the model the activation of candidate words is a graded process. Candidate words are not completely eliminated as acoustic information accumulates, but rather they have their activation level reduced. This can rise again if later acoustic information matches a rejected candidate word. This is important, as one of the problems of conversational speech is that individual words or phonemes are often not articulated clearly and the listener must be able to recover and recognize words whose initial sounds were mispronounced or misheard in a noisy environment.

The main competitors to speech recognition models are various connectionist accounts, notably Trace (McLelland and Elman, 1986). This is a connectionist or parallel distributed processing (PDP) account of spoken language processing. In such models researchers were attempting to produce computational models of language processes which were inspired by what was known about the structure and processes of the human brain. In spoken word recognition models, this meant that the feature units were simple units with dense series of interconnections, which processed by sending many messages in parallel. Such structures were developed as analogous to the neural architecture of the brain with its many nerves and interconnections.

The Trace model has three layers of units, corresponding at the lowest level to features, then at the next layer to individual phonemes, then at the top layer to complete words. All have dense arrays of interconnections between them, which like nerve pathways can be excitatory or inhibitory. The connections between levels are excitatory and connections within levels are inhibitory. Connections between levels operate in both directions, so both top-down and bottom-up processing can occur. The connectivity of Trace means that evidence is boosted and plausible hypotheses about the possible words emerge strongly. So a feature such as voicing will energize the voice feature units. These will then transmit activation to all the voiced phonemes at the phoneme level, which will in turn activate all the words that begin with these phonemes. At each level the activated units inhibit competitors at the same level, so reducing

possible competitors. A word is recognized when in the end a single active unit remains.

Trace is a very interactive model. It gives context a bigger role in recognition than the cohort model. As a computational model it has the virtues of specificity. Trace models can be built and simulations run and then compared with the experimental data from human listeners. These comparisons have generally shown that Trace can cope with some of the problems of variability in production of features and phonemes, can account for the context effects on spoken word recognition that have been reported in the literature, and can cope with the kind of degraded acoustic input that is so typical of real conversational speech. The main criticisms that have been leveled at Trace concern the large role that context is given, which may be an overstatement of how this operates in human recognition. The other limitation is the less than elegant way that the time course of speech recognition is modeled, with duplication of the levels and nodes over successive time periods.

Other connectionist models have also been developed. Despite the competing architectures of the models, there is general agreement on key aspects of the speech recognition process. This involves activation of multiple candidate words, followed by competition among those known lexical items that share a similar sound profile; these processes have to be able to cope with less than ideal acoustic input and deliver perceptions of words very rapidly.

Discourse Processing

The gradual broadening of the psycholinguistic research agenda has not been limited to the inclusion of speech alongside written language. Psycholinguists have also shown a growing interest in the processes involved in the interpretation not just of single sentences, but of complete texts. One of the first psychologists to explore the complexities of this process was Bartlett (1932). In his research on the way people remembered and reproduced stories that they had heard, he highlighted key research themes in discourse processing that are still current research topics. Bartlett noted how quickly the surface form of the story is lost and an individual's own interpretation of the text is what is remembered. He introduced the concept of a 'schema,' which was used when readers recalled a narrative. This consisted of an organized set of information based on prior experiences that is used in interpretation and recall. The interpretation of a narrative that is retained consists of a mix of input from the text and from schemata. In some of Bartlett's studies, British students listened to North American folktales. When asked to recall the stories accurately,

strange narrative details relating to the activities of ghosts were unconsciously altered and supplemented by details from the participants' world knowledge, so that the recalled version of the stories became more coherent by conventional Western standards.

More recently, a growing body of psycholinguistic research has been addressing the challenges of how readers build up a coherent mental representation to create a sense of the narrative world. One of the key concerns of psycholinguistic studies of text or discourse processing is the problem of inferences. Since Bartlett's seminal studies, it has been known that readers expand on what is in the text by drawing inferences based on their knowledge of the world. But what are the time course and limits of such inferencing? Many studies have been concerned with addressing such questions. Experimental studies have shown that some inferences seem to be made automatically as we read a text while some are made later to resolve apparent problems or inconsistencies. This was demonstrated in a study by Sanford and Garrod (1981), who presented readers with pairs of sentences such as the following:

- (4a) Mary was dressing the baby.
- (4b) The clothes were made of wool.
- (5a) Mary was putting the clothes on the baby.
- (5b) The clothes were made of wool.

The participants read the second sentence just as quickly in both cases. This suggests that verbs such as 'dress' cause readers to automatically draw the inference concerning 'clothes.' In contrast Haviland and Clark (1974) found that some inferences took a small but significant amount of time during reading. In their experiment they used pairs of sentences like the following:

- (6a) Harry took the picnic things from the trunk.
- (6b) The beer was warm.
- (7a) Harry took the beer from the trunk.
- (7b) The beer was warm.

They found that sentences like (6b) took longer to read than (7b), because the readers had to make the backward inference that the beer was part of the picnic supplies.

Researchers wished to determine the limits on the kinds of inferences which are made immediately and automatically and which are made later. Clearly, there must be limits on the amount of background knowledge readers activate and one of the research goals is to understand what these limits are and the cognitive processes which support this. Models have been developed that attempt to specify the way inferences are made and the way coherent mental representations are derived from texts.

Although there are significant differences between the models, there are several agreed features of how discourse processing operates in terms of the way readers update their mental representations of a text, the way some information is held in the foreground of processing while others is background, and the way that certain inferences are drawn automatically to maintain a coherent account of the text. For details of the various models of discourse processing that have been proposed (see **Discourse Processing**).

Reading as a Developmental and Educational Process

Before an interpretation of a written text can be made, the words on the page have to be read. Although apparently effortless for the skilled adult reader, the processes of identifying letters, recognizing words, and thus distinguishing the meaning conveyed in even a simple sentence, are complex. One key to unraveling how this is accomplished has been to study readers' eye movements. These have been shown to be very systematic and to consist of three main types: short forward movements of around 6–9 letters called saccades, which last on average 20–50 ms; backward movements called regressions; and the pauses or fixations when the readers' eyes rest on a word for around 250 ms.

Rayner and colleagues have shown there are consistent patterns in these movements (see e.g., Rayner, 1998). When reading more difficult texts, fixations grow longer, saccades grow shorter and regressions become more frequent. Even within a single text, readers will spend more time fixating relatively uncommon words compared to familiar ones. Eye movements are designed to keep the middle of our visual field, where our vision is best, aimed at new areas of interest. However, we are able to distinguish quite a lot of information within a single fixation. A skilled adult reader of English will usually be able to identify 15 letters to the right of the fixation point but only three or four letters to the left.

When children begin to learn to read they fixate words for longer than skilled readers. They also have a shorter perceptual span than adults, which means that in a single fixation they are able to identify fewer letters. Gradually these patterns approach those of adults as reading proficiency increases. The typical English reader's asymmetric perceptual span starts to appear in most young readers within a year of starting to learn to read. This seems to reflect the left-to-right nature of reading English, as readers of Hebrew, which is read right to left, show the opposite pattern in their perceptual spans. Like much of psycholinguistics, the study of skilled reading has largely

been the study of skilled English reading but more recently interesting studies have been conducted on other languages, notably on nonalphabetic scripts such as Chinese and Japanese.

Visual Word Recognition

One aspect of the reading process has received a great deal of research attention in psycholinguistics: the process of visual word recognition. A whole set of phenomena have been identified in the processes of recognizing written words. These include the process of priming. Words are recognized more quickly if they have been read previously. This is known as repetition priming. Words are also recognized more quickly if a word of similar meaning has just been presented, so 'butter' is recognized more quickly if 'bread' has just been read. This is known as semantic priming. Priming can also occur between words which do not seem to have a direct semantic relationship, such as 'music' and 'kidney,' which are linked by an intermediate word 'organ,' which was not presented to the readers.

Other phenomena which researchers have identified in word recognition include the fact that words which are common in the language, such as 'road,' are recognized more quickly than similar words that are less common, such as 'rend.' This word frequency effect is a strong influence on recognition speeds, with even fairly small differences in word frequency influencing reaction times. It is the most robust effect in studies of word recognition, appearing in many different studies using a wide variety of research methods.

These and other phenomena about how words are recognized have been used to develop a variety of models of word recognition. These can be grouped into families of related accounts. Some of the proposed models are direct access models, where perceptual information goes straight to feature counters or units. Other accounts propose that perceptual information is used to trigger a search through the mental lexicon, that is, the stored representation of all the words known to the reader.

One of the best-known serial search models was proposed by Forster (1976). In this account, the perceptual input is used to build a representation of the word to be recognized which is then checked in two stages by comparisons with a series of access files, which are analogous to the cards in a library index system. Once an input string is matched to an access file it is then linked to the master files, analogous to the books on the shelf, which contain the full lexical entries for each word. The files are organized to speed up the process of word recognition, with groups of files being arranged in bins that contain similar words. Within a bin, files are organized by

word frequency. The details of the model are described to account for the observed features of the recognition process. For example, there are cross-references between master files that would support semantic priming. Despite these features it is not clear that this kind of serial search model can convincingly account for the speed with which words are recognized. It has also been criticized as being based on a rather dated analogy with the cognitive system as a digital computer rather than as a neural system.

More recently, however, Murray and Forster (2004) have published an account of a series of word recognition studies that are claimed to show strong support for the serial search model. They claim that the structure within bins, notably the **rank** ordering of words within a bin in terms of frequency, accounts for the pattern of experimental results on word frequency effects more parsimoniously than alternative direct access models.

More popular models of word recognition involve direct access from the sensory information to the lexical units. One of the most influential of the early accounts of this sort was the Logogen Model (Morton, 1969). In this model, perceptual information, either from visual or auditory analysis, feeds directly into the logogen system. This consists of a series of units, logogens, which represent known words. Logogens act as feature counters and when a logogen has accumulated sufficient evidence to reach a threshold it fires. A word then becomes available to the output buffer, is recognized, and can be articulated. The logogens receive input from the cognitive system as well as the sensory input routes and so the resting threshold of the logogen can be varied by, for example, prior experience of a word, or from the sentence or discourse context. Common words with which an individual has had a lot of prior experience will have a lower threshold and will fire with less sensory input and hence be recognized more quickly. Similarly, words that are highly predictable from context will also have their thresholds raised and so will be recognized rapidly.

The Logogen Model has been used as the basis of computational models of word recognition, notably the interaction activation model (IAM) proposed by McClelland and Rumelhart (1981). This was one of the early connectionist or PDP accounts of language processing. Researchers were trying to produce computational models of language processes which were inspired by what was known about the structure and processes of the human brain. In word recognition models, this meant that the feature units were simple units with dense series of interconnections, which processed by sending many messages in parallel. The IAM consisted of three layers of units,

corresponding at the lowest level to the visual features of letters, then at the next layer to individual letters, then at the top layer to complete words, all with dense arrays of interconnections between them, which like nerve pathways could be excitatory or inhibitory. The model was able to account for a wide range of experimental observations on word recognition.

Models of this type have become very widely used in psycholinguistics to explore a wide variety of language processes. This trend towards testing computational models against the existing experimental literature in a way that can link to new insights about the neural processes involved in language and cognitive processes is a popular approach in current psycholinguistics.

Dialogue and Gesture

In parallel to this concern with understanding the cognitive processes and the possible neurological architecture involved in language processing has been a growing interest in language processing in context. This means not only the growth in studies of how extended texts are processed but also a developing field of psycholinguistic studies of interactive language use. These studies have focused on language in its natural setting, interactive dialogue.

Dialogue represents the most ubiquitous form of language use. As young children, we learn to use language through dialogues with our parents and caregivers. Even educated adults spend a great deal of their time in conversations with family, friends, colleagues. Spoken dialogue is still used to obtain many forms of goods and services. In the many non-literate cultures in the world dialogue is the main or only form of linguistic interaction.

Yet till recently dialogue received rather little research attention in psycholinguistics. One of the challenges for psycholinguists who wished to study dialogue was to derive methods of exploring the phenomenon which would produce testable and generalizable research questions and findings. One experimental method which has been used to allow the study of comparable dialogues from many pairs of speakers is the referential communication paradigm, developed by Krauss and Weinheimer (1964). In this, pairs of speakers are presented with an array of cards depicting abstract shapes. The speakers have to interact to determine which card a speaker is referring to at a given point in the dialogue. These early studies revealed key aspects of dialogue, including the way that over the course of a dialogue, the lengths of descriptions of even complex and abstract stimuli become much shorter and more concise.

The interaction between the speakers was found to be crucial in this process. If this interaction was disrupted the speakers were not able to reduce their descriptions to the same extent.

Later studies on referential dialogues were conducted by Clark and colleagues. In one influential paper, Clark and Wilkes-Gibbs (1986) developed a collaborative model of dialogue. From studying many pairs of speakers engaged in dialogues, they highlighted the way speakers work together through their contributions to dialogue to arrive at a shared and mutual way of referring to things they wish to discuss. This means that the speaker and the listener both take responsibility for assuring that what has been said is mutually understood or 'grounded' before the dialogue proceeds.

In this view of dialogue, speakers follow the principle of collaborative effort and try to minimize their overall effort in arriving at an agreed description. This is done iteratively over a number of turns of speaking, often with each speaker contributing part of the description. This process makes use of the opportunities and limitations of spoken dialogue in a way that highlights its differences from written language. In text, the writer can take as much time as is needed to produce a description that she thinks the reader will understand. In dialogue, however, the speaker is under time pressure, as conversation rarely allows long gaps in which to plan an utterance. The speaker therefore has to produce an immediate description and may not be able to retrieve the most appropriate description or judge what way of describing a referent will be interpretable by the listener. The advantage of dialogue, however, is that the speaker and the listener can work together to refine or clarify the speaker's initial description till they both share a common understanding.

The highly collaborative nature of this process is reinforced in two key studies by Clark and colleagues. Clark and Schaefer (1987) showed how contributing to dialogue is characterized by two phases. Each time a speaker wishes to make a contribution, they produce a stretch of speech that is the content of what they wish to contribute. This is called the presentation phase. They then require an acceptance phase, in which their listener gives evidence of understanding the previous contribution. So the dialogue involves two activities: content specification and grounding, that is attempting to ensure that both speakers understand the content sufficiently for their current conversational purposes.

The importance of the ability to actively contribute to the dialogue interaction was demonstrated in a study Schober and Clark (1989). Using the referential paradigm they had pairs of speakers complete

the task. An additional participant was included in each interaction who overheard everything that was said but did not take part in the dialogue. This overheard had a much harder time trying to identify the intended referents of the descriptions than the conversational participant, despite having the same pictures and having heard everything that was said. The suggested explanation is that the descriptions were not grounded for the overhearers. They had no chance to collaborate and ensure that they understood each description as it emerged during the dialogue.

So there is clear evidence that dialogue is an interactive and collaborative process that involves speakers and listeners attempting to cooperate and achieve mutual understanding. The detailed mechanisms that underpin these general processes of adaptation to the interlocutor are now the focus of a good deal of psycholinguistic study. There is some controversy over the extent to which speakers are able to adjust and adapt their output to their listener's needs. In terms of the forms of referring expressions chosen by speakers there is evidence of adjustment to the listener's general level of knowledge of the domain. When it comes to adjusting the intelligibility of their articulation, speakers seem to be largely egocentric. They reduce the clarity of their word production in terms of what is familiar to them as speakers rather than modeling their listeners' needs. The time course of adaptation is also debated, with some studies showing speakers initially produce utterances from their own perspective but later monitor their listeners and adapt. Other studies show listener adaptations from the start of speaking.

As language processing is studied in more natural contexts of use, it becomes clear that speakers and listeners do not just communicate using the verbal channel. Visual signals from the mouth, face, hands, and eyes are all important features of communication. Researchers have begun to explore the way the visual channel is used by speakers and listeners and the relationship between verbal and visual signals.

More generally, in a dialogue, what we say, how much we say, and even the clarity of the way the words will be spoken have all been shown to change when speakers do or do not have access to visual signals. So speakers who can see one another need to say less to complete a task, use more gestures, can exchange turns of speaking more smoothly, and articulate their words less than when they cannot see one another.

The important role of visual signals in the perception of speech and how these are integrated with acoustic information is a fascinating research area. This was highlighted in a seminal study by McGurk and MacDonald (1976). They demonstrated that

when a listener hears a phoneme such as 'ba' while watching a face mouthing 'ga,' the sound which is heard is a fusion 'da.' This is a powerful illusion that occurs even with knowledgeable listeners/viewers and has been demonstrated with young babies.

The role of visual signals in the production and comprehension of more extended stretches of discourse has also been the subject of considerable study. From studies of conversation and storytelling, the important role of gestures and their relationship to the accompanying speech has been established. For some kinds of gestures there is a close temporal relationship with the accompanying speech. Listeners also seem to fuse information presented visually and verbally. If they are told a story by a speaker who uses speech and gesture and are then asked to retell the story later, information originally presented by gesture, such as the speed of an action or the manner of leaving, is often relayed in speech and vice versa (for more information **Gesture and Communication**).

Future Directions in Psycholinguistics

Several trends seem apparent in psycholinguistics. Some of these seem to be the result of improvements and developments in the research methods available to psycholinguistics. One is an increased interest in detailed investigations of language in richer, more naturalistic, contexts. New research techniques such as improved methods of tracking a speaker or listener's eye movements mean, for example, that studies of dialogue, or the relationship of a speaker's production to the surrounding context, can be studied with the precision that used to be only possible in studies of isolated word recognition or sentence processing.

Improvements in the ease and accessibility of various brain-imaging techniques mean that these are being used not only as contribution to our understanding of the neural substrate of different language processes. Techniques such as ERP (event-related brain potentials) can now be used more and more as means to explore the precise time course of language processing. Newer techniques such as MEG (magneto-encephalography) are beginning to offer psycholinguists not just good information about the temporal patterns of language processing but also detailed information about the location of associated brain activity. The growing interest in the neural substrates which support language processing has received a major boost from the development of these new forms of brain imaging.

The interest in how to build neurologically plausible models was of course one of the drivers behind the expansion over the last 20 years in connectionist

models of language. These have made a major contribution to our understanding of how a wide variety of language processes, such as spoken or written word recognition, might operate and be learned. The challenge in the future will be to see whether connectionist models can be implemented for more extensive language processing, such as text comprehension or contribution to dialogues. The way such models can or cannot be scaled up to simulate more complex language processing will be one of the key challenges for the next few years.

In the future psycholinguistics will also need to address its undoubted Anglocentric bias. The vast majority of studies of language processing are in fact studies of English language processing. In a number of areas a few studies are emerging which consider other languages but this effort needs to be greatly increased. Over the last 50 years psycholinguistics has expanded dramatically and made considerable progress in understanding a wide variety of language processes. With new research techniques and a more balanced research portfolio in terms of the languages studied and the research efforts applied to production as well as comprehension, spoken as well as written language, future progress seems assured.

Queer Language and Queer Linguistics

The word 'queer' has been used in a variety of ways (see McConnell-Ginet (2002) for a detailed discussion). In the early 20th century in the United States, the term queer was used as a term of self-reference (or identity category) for homosexual men who adopted masculine behavior (Chauncey, 1994: 16–18). By the 1970s, 'queer' had been appropriated by heterosexuals as a pejorative and ceased to be used as a term for self-reference by homosexual men. In the late 1980s and early 1990s, a political activist organization known as Queer Nation attempted to reclaim 'queer' as a general term for sexual and gender minorities. The term was subsequently taken up in academic writing in the emerging field of queer theory, an extension of theoretical work in feminist theory that deals with issues of sexuality, sexual identity, and gender identity. The term queer has since been used in different and often conflicting ways. As originally used in queer theory, the term queer was not intended as an identity label to refer to a particular externally defined group. Queer theorists rejected terms such as 'gay' or 'lesbian' as inherently exclusionary and argued that identity categories marginalize individuals who are not prototypical members of a given identity category. The use of 'queer' was intended as a means of rejecting identity labels by proposing a term that referred to all individuals who were marginalized in some way by heteronormativity, the social norms associated with hegemonic heterosexuality. Thus, 'queer' includes (but is not restricted to) all sexual and gender minorities. In this usage, the actual membership in a 'queer' community is left intentionally vague because 'queer' is defined not in terms of who belongs but in terms of what queers react against. Thus, the common denominator for queers is their marginalization and exclusion rather than being unified by some common identity or shared social practices. The 'queering' of academic disciplines was proposed as a means of turning attention toward those individuals who

had been traditionally marginalized in social theory. By focusing on individuals who are not prototypical members of traditional (etic) identity categories, queer theory attempts to gain insight into the normative forces that underlie social practice. Research that falls within the realm of queer linguistics does not always deal with speakers who are gay, lesbian, or transgendered but may deal with speakers who are marginalized in other ways, as with Mary Bucholtz's (1999) research on the language of self-proclaimed 'nerds.'

Within linguistics, this use of 'queer' has been adopted by those working in 'queer linguistics' (Barrett, 1997, 2002; Bucholtz and Hall, 2003, 2004; Hall, 2003; Livia and Hall, 1997a) in an attempt to adopt and amend proposals from queer theory into a framework for the study of language. Although 'queer' within queer linguistics was intended to refer to queer theory (rather than any community of actual queers), this use of 'queer' has been criticized primarily on the grounds that it does not refer to any externally definable social group (Kulick, 2000; Leap, 2002). In contrast to sociolinguistic frameworks focusing on norms of language variation that categorize individuals into speech communities based on etic identity categories, queer linguistics assumes that speech communities are prototype categories that do not have clearly definable boundaries. The field of queer linguistics emphasizes the language practices at the margins of traditional approaches in order to examine how membership in particular speech communities is negotiated and contested (Bucholtz and Hall, 2003, 2004). Central to queer linguistics is the view that the indexical meanings associated with linguistic variables are performative in that they may create both speaker identities and social contexts. By using particular linguistic variables, speakers may associate themselves with (or in opposition to) particular identity categories and norms for the interpretation and use of indexical meanings (Bucholtz and Hall, 2003, 2004) (*see Pragmatic Indexing*).

In usage outside of academic writing, the term queer is often used as a cover term to refer to gay, lesbian, bisexual, and transgendered people. However, recent

usage suggests that in public discourse 'queer' may be shifting toward use as an androcentric generic, similar to 'man' or 'gay' (Cohen, 2002). Rather than attempt to discuss the language of a hypothetical group of queers, the remainder of this article focuses on studies that have been central in the development of queer linguistics, including gay and lesbian language use, transgendered language, and the role of language in maintaining heteronormativity.

The Study of Gay Male and Lesbian Language

The study of gay male ways of speaking first emerged in the early 20th century (see Cameron and Kulick (2003) for a summary of the history of this research). During this period, male homosexuality was understood largely in terms of gender expression, and men and women who displayed normative gendered behaviors were not generally considered homosexual, even if they engaged in sexual acts with members of their own sex (Chauncey, 1994). Early work typically viewed homosexuality as a psychological disorder and usually involved collecting lexical items from the 'secret' argot of homosexual men. Because gay male language was seen as a byproduct of deviant sexuality and gender expression, research focused primarily on sexual vocabulary and the alternative use of gendered language, such as the use of female pronouns and feminine proper names by gay men. During this period, the language of lesbians received much less attention, given the centrality of effeminate men in prevalent understandings of homosexuality.

In the years before and after World War II, views of homosexuality shifted so that 'gay' identity was understood in terms of sexual practices rather than gender expression. It was during this period of research that current debates about gay and lesbian language began to emerge. Whereas some linguists saw gay male and lesbian language as a unique form of cultural expression, others viewed gay and lesbian 'argot' as a result of oppression and marginalization. Those who favored assimilation and believed that gay men and lesbians should differ from heterosexuals only in terms of sexual practice viewed homosexual 'slang' as a byproduct of oppression against homosexuality.

After the Stonewall riots in New York in 1968 and the passage of the 1967 Sexual Offences Act in the United Kingdom, the gay and lesbian civil rights movement began to gain ground. During the 1970s, research on gay male language continued to focus primarily on lexical items and gender crossing. Building on the 'ethnic model' of the civil rights movement, linguists typically viewed gay male language as a

basic component of gay and lesbian culture. During this period, scholars such as Bruce Rogers (1972) and Julia Penelope Stanley (1970) collected extensive vocabularies of lexical items that were typically seen as reflecting the unique cultural identity of gay and lesbian speakers. Some scholars, however, continued to view gay and lesbian language as a secretive argot (Farrell, 1972).

The first major collection of research specifically examining gay and lesbian language was *Gayspeak* (Chesebro, 1981). This collection laid out many of the debates that had been building in the field and continue into more recent research (Barrett, 2003). Hayes (1981) argued that 'gayspeak' was an authentically gay way of speaking that differed from heterosexual language in three particular contexts: the 'secret setting,' the 'social setting,' and the 'activist-radical setting.' In the secret setting gay men use particular forms of language to convey their sexuality to one another without making their sexuality known to heterosexuals who might hear their conversation. Painter (1981) also described this type of covert communication among lesbians. In the social settings, Hayes described the use of specific vocabulary and discourse styles associated with contexts in which all participants were gay, whereas the activist-radical setting referred to the language of the gay and lesbian civil rights movement. In responding to Hayes, Darsey (1981) questioned the existence of gayspeak, arguing that the structures described by Hayes were not unique to gay or lesbian communities. Like earlier scholars who believed that the unique elements of gay language resulted from resistance to social stigma, Darsey argued that gay male language was not particularly different from the language used by other marginalized groups.

The debate between Darsey and Hayes resurfaced in response to the work of William Leap (1996). Leap followed Hayes in arguing for an authentically gay male language, gay men's English, that differs from the language of heterosexuals. Leap described gay men's English largely in terms of norms for interaction such as the use of cooperative discourse. Kulick (2000) followed Darsey in claiming that none of the structures described by Leap are unique to gay men and, therefore, gay men's English does not exist. However, Leap openly admitted that his view of gay men's English is restricted to a specific subset of gay men, namely white middle-class men in the United States. Leap argued that although gay men's English does not reflect the language of all gay men who speak English, it is an important marker of gay identity for many speakers and has spread to other groups of gay men with the globalization of Western views of homosexuality (Leap and Boellstorff, 2004).

Work in queer linguistics proposes an alternative to this argument (Barrett, 1997; Queen, 1997), arguing that although the linguistic structures of gay and lesbian language overlap with the speech of other social groups, it is more likely that the distinctive character of gay and lesbian language might be found in the ways in which those structures are combined (instead of the structures themselves). For example, Harvey (1998, 2000) analyzed what he called ‘camp talk’ as a set of rhetorical devices that produce a style that indexes gay male identity. Harvey argued that camp talk involves four basic linguistic strategies: paradox (the juxtaposition of contradictory or conflicting meanings), inversion (the reversal of the expected meanings of signs, such as the use of ‘she’ to refer to a man), ludicrism (utterances that highlight ambiguity or indeterminacy in meaning), and parody (forms that exaggerate stereotypes about speaker orientation). In Harvey’s analysis, the linguistic structures involved are not uniquely gay, but the way in which particular structures are combined serves to index gay male identity.

Structural Aspects of Gay Male and Lesbian Language

Although current views of homosexuality distinguish gender expression from sexual orientation, stereotypes of gendered language use continue to play an important role in the perception of speech as ‘gay’ or ‘straight.’ Several studies have examined the linguistic features stereotypically associated with gay male or lesbian speech (see Jacobs (1996) for a review). Although some of this research suggests that these features may be used by listeners in perceiving speech as gay or straight, researchers have found no direct correlation between these forms and actual use by those who identify as gay or lesbian. The phonetic aspects of speech that are stereotypically perceived as ‘gay male’ in English include hyperstandard pronunciation, such as longer duration of sibilant fricatives and /l/ (Crist, 1997), a longer voice onset time for voiceless aspirated stops, and the release of word-final stops (Podesva *et al.*, 2002). Also, a wider intonational pitch range is often associated with stereotypical gay-sounding speech (Gaudio, 1994; Smyth *et al.*, 2003). In contrast, stereotypes of lesbian speech include a narrow pitch range and ‘flat’ intonation patterns (Moonwomon, 1997; Queen, 1997).

These stereotypes of gay male and lesbian speech often reflect stereotypes of gendered language use. This is the case, for example, with syntactic and lexical variation. Gay male speech is often viewed as having hyperstandard speech and using lexical items stereotypically associated with women, whereas

lesbian speech is often associated with male stereotypes, such as nonstandard or working-class speech and the use of obscenities. Although these features do not reflect actual usage by gay men and lesbians, speakers may use these linguistic stereotypes to convey sexual orientation in specific contexts. Livia (1995), for example, demonstrated how literary representations of lesbians rely on stereotypes of ‘men’s language,’ including limited responses, avoiding expressions of emotion, and the use of sexually explicit vocabulary. A number of research questions remain largely unexplored, including a more detailed understanding of when and how these stereotypes are exploited by gay men and lesbians, whether or not (and how) they might be used by speakers who identify as bisexual, and the various indexical meanings listeners associate with specific variables that have been associated with stereotypes of sexual orientation.

Gay and Lesbian Lexicons

Most early studies of gay male and lesbian language use focused on ‘homosexual slang,’ or the lexical items unique to gay and lesbian communities. A number of researchers have published lexicons of terms used in gay and lesbian communities (Baker, 2002a; Cory, 1965; Legman, 1941; Stanley, 1970; Rodgers, 1972). Many early researchers viewed gay and lesbian vocabulary as a mechanism for dealing with the stigma of homosexuality. Some viewed gay/lesbian slang in a positive light, holding that unique vocabulary was a survival strategy creating a social space in which being homosexual was acceptable. Others viewed the gay/lesbian vocabulary as a negative result of social marginalization that continued to exclude gay men and lesbians from larger society, whereas others argued that gay vocabulary was not simply a mechanism for dealing with stigma but that it was a means of defining social roles in gay and lesbian communities (Kulick, 2000). As is common in research on homosexual language, these studies typically gave comparatively little attention to lesbian vocabulary.

The most well-known and structurally distinct gay male language variety was Polari (Baker, 2002b) used in the United Kingdom. Polari evolved from a variety of sources, including Lingua Franca as used by English sailors, the language of those working in the entertainment industry, Cockney rhyming slang, and the language of prostitutes. Although Polari contains some unique syntactic patterns (Baker, 2002b: 52–56), the primary difference between Polari and other varieties of English is the use of a unique vocabulary. The vocabulary of Polari, however, is unique among

gay/lesbian varieties in that it is so extensive as to be unintelligible to the majority of English speakers, as in the following example (Baker, 2002b: 53):

Polari: varda the naff hommie with nante
pots in the cupboard
Translation: look at this unsightly wretch with the
appalling dentistry

Use of Polari has declined dramatically since the 1960s. The lack of knowledge of Polari among younger speakers leads Baker (2002b: 109–111) to conclude that Polari is a dying language.

The decline of Polari is related to the shift in understandings of homosexual identity from being based primarily on difference in gendered behavior to being based on sexual attraction and behavior. The culmination of this shift in the gay and lesbian civil rights movement led to a period in which gay male identity was typically conveyed through behaviors that reflected a unique form of masculinity rather than through stereotypical ‘feminine’ behavior (Levine, 1998). The backlash against camp or feminine behavior during the 1970s and early 1980s led to a similar decline in the use of many gay male lexical items in the United States. The rejection of in-group language that was viewed as feminine did not, however, end the use of in-group forms of communication but led to the formation of new systems of in-group communication. For example, in the 1970s the ‘hanky codes’ emerged in the ‘clone’ community in the United States. The hanky codes involved the use of colored bandanas in one’s back pocket as a way of signaling preferences for particular sexual acts. For example, light blue signified a preference for oral sex, whereas dark blue signified anal sex. Bandanas worn on the left side indicated a preference for being the active partner (or ‘top’), whereas those worn on the right side indicated a preference for being the passive partner (‘bottom’) (Levine, 1998: 65–66).

Gay Male and Lesbian Discourse

Given that grammatical features associated with gay and lesbian language seem to be related to stereotypes rather than actual usage, a number of linguists have focused on gay and/or lesbian norms for structuring discourse and conversational interaction instead of the use of particular linguistic structures (McIlvenny, 2002). Studies of both gay male and lesbian discourse have tended to focus on the collaborative nature of gay and lesbian interaction. Although collaborative discourse is certainly not unique to gay or lesbian speakers (*see Cooperative Principle*), some linguists have argued that gay men and lesbians use cooperative norms for interaction as a means of asserting a

shared identity based on sexual orientation. The most distinctive aspect of this cooperative discourse is the assumption of shared cultural knowledge associated with sexual orientation. Studies have highlighted the role of cooperative discourse in the affirmation of both gay male (Leap, 1996) and lesbian (Morgan and Wood, 1995) identity as well as the role of cooperative discourse in asserting shared identity between gay men and lesbians (Queen, 1998a, 1998b). In a detailed study of crosssex conversation between gay men and lesbians, Queen (1998b) found that although speakers used language to form a unified identity as homosexuals based on shared cultural knowledge, gay men and lesbians also used structures stereotypically associated with gendered conversational styles. Although an assumption of shared cultural knowledge may be important in particular contexts, it is not the case that all gay or lesbian interactions are necessarily ‘cooperative.’ For example, several studies have examined the genre of verbal dueling and the use of ritual insults among gay men (Goodwin, 1989; Murray, 1979; Read, 1980).

Another aspect of gay and lesbian discourse that has received a great deal of attention is the ways in which gay men and lesbians convey sexual orientation to one another through the use of conversational implicature (*see Implicature*) (Hayes, 1981; Leap, 1996; Liang, 1999; Painter, 1981). As with cooperative discourse, this use of implicature is not uniquely gay or lesbian but relies on the assumption of shared knowledge of gay or lesbian cultural norms as a means of conveying sexual identity. Speakers may use implicature to convey homosexual orientation such that the actual meaning (‘I am gay/lesbian’) can only be inferred if the listener has some prior knowledge of gay/lesbian culture. Such a use of implicature allows gay and lesbian speakers to reveal their sexual orientation to one another without necessarily revealing themselves to heterosexuals involved in the same conversation. A speaker might, for example, respond to a question about how one spends his or her free time by referring to spending time in a particular neighborhood with the understanding that only other gay men or lesbians will recognize that neighborhood as a center of gay/lesbian culture. Similarly, before the use of the term ‘gay’ became widely recognized as meaning homosexual, men might have used the word to convey their sexual orientation to one another with the assumption that heterosexual listeners would not likely understand that the word referred to sexual orientation, as in the following example from Hayes (1981: 46):

Mr. X: You certainly have a colorful tie.
Mr. Y: Yes, I really like gay apparel.

Another aspect of gay and lesbian discourse is the use of particular verbal genres such as ritual insults or verbal dueling. The most widely studied genre associated with gay and lesbian speakers is the 'coming out story.' 'Coming out (of the closet)' refers to the act of revealing one's homosexual identity. There are competing notions of what exactly it means to be 'out' (i.e., openly homosexual), and one may be 'out' in particular social contexts and 'not out' in others (Zwicky, 1997). Studies of coming out stories in a variety of local communities have found strikingly similar structure in the genre (Liang, 1997; Maher and Pusch, 1995; Wood, 1997, 1999). Coming out narratives typically include the following stages (Liang, 1997):

1. Recognition of the processual nature of coming out
2. Coming out to self
3. Coming out to other

As with concepts such as cooperative discourse or the use of implicature to convey sexual identity, the coming out story is founded on assumptions of shared knowledge of gay and lesbian cultural norms. One common feature of studies of gay and lesbian discourse is the critical role of a shared sexual identity in establishing cultural norms for language use.

Transgendered Language

The term 'transgender' is an umbrella term for individuals who display behavior patterns typically associated with the opposite sex, including transsexuals, drag queens/kings, and transvestites. Transsexuals are those who believe that the sex they have been assigned based on physical appearance does not correspond to their psychological and social experience. Some transsexuals undergo sex-reassignment surgery to repair the dichotomy identity vs. biology. In terms of language, transsexuals typically attempt to adjust their speech patterns to reflect normative expectations of gendered use of language. For male-to-female (MTF) transsexuals, language is a central component in changing one's gender identity. MTF transsexuals typically adopt stereotypes of gendered language use and may undergo speech therapy in order to sound more feminine. The move toward stereotyped 'women's language' typically involves raising the pitch of one's voice, using a wider range of intonation patterns, speaking more softly, and using lexical items stereotypically associated with women's language. Although research on MTF transsexuals almost always includes a linguistic component, the language of FTM (female-to-male) transsexuals receives very little attention. This is often explained by the fact that the

testosterone taken by FTM transsexuals thickens the vocal chords, lowering a speaker's pitch. Thus, it is often assumed that learning to speak 'like a man' is not a problem for FTM transsexuals. However, the lack of attention given to FTM speech is also tied to an ideology in which men's language is unmarked with respect to women's language (Kulick, 1999).

Although the language of transsexuals is typically seen as reproducing stereotypes of gendered language, other forms of transgendered language seem to center around undermining these stereotypes. Drag queens (gay men who dress in women's clothing) often use stereotyped women's language, but often mix stereotypically masculine forms into their feminine speech. African-American drag queens, for example (Barrett, 1998, 1999), typically juxtapose linguistic forms that stereotypically index identities that are in opposition. For example, a speaker may use stereotyped feminine 'ladylike' speech mixed with obscenities or juxtapose language that indexes a white middle-class identity with forms from African-American English. Although the use of feminine speech for MTF transsexuals is an attempt to change general speech patterns in all situations throughout one's life, the use of feminine speech for drag queens is temporary and highly dependent on social context.

Descriptions of linguistic forms that index a speaker's gender have noted transgendered speech in a variety of languages. A number of Native American languages contain grammatical elements described as corresponding to the gender of a speaker. Most of the descriptions note that there are 'exceptional' speakers who sometimes use the forms corresponding to the opposite gender (Hall, 2003). Detailed research on Lakhota (Trechter, 1999) suggests that use of gender-marked elements by members of the opposite sex does not simply convey a transgendered identity. Rather, the meaning of gendered elements is highly dependent on context and may convey personal attributes other than gender. Hall and O'Donovan (1996) also found that Hindi-speaking *hijras* use grammatical gender marking to convey a variety of indexical meanings. Whereas hijras generally use forms marked as feminine for self-reference, they use masculine forms when foregrounding positive personal attributes associated with masculinity (e.g., owning a home or being trustworthy). Rudes and Healey's (1979) study of the uses of 'he' and 'she' by gay men in the United States also found that gendered pronouns were associated with particular indexical meanings. Although 'she' was used in positive references to physical attractiveness, most uses of 'she' were associated with negative attitudes toward the referent.

An important insight of this research has been the confirmation that the indexical meanings associated with gender are indirect (Ochs, 1992). Even in languages in which particular linguistic structures have been assumed to be direct markers of speaker gender (e.g., Lakhota or Hindi), these structures do not necessarily directly refer to speaker (or referent) gender. Rather, the structures associated with gender index particular social attributes, stances, or personality traits that are in turn associated with cultural assumptions about the particular attributes that are associated with masculine or feminine behavior. For example, Eckert (2002) noted that in American English, the release of word-final stops has been associated not only with the speech of gay men (Podesva *et al.*, 2002) but also with indexing 'Jewish speech' and the identity of female nerds. Rather than directly marking a given sexual identity or gender, released final stops seem to index something like "articulateness" (Eckert, 2002: 102). The relationship between indexical meanings and social categories is not direct, but it is negotiated through indexing attributes that may in turn be associated with social categories.

Language and Heteronormativity

A final aspect of queer language is the role of language in maintaining heteronormativity, or the social norms that enforce hegemonic (compulsory) heterosexuality and marginalize gay, lesbian, or transgendered speakers. Although there is no *a priori* reason to assume that there is any relationship between norms for gendered behavior and sexual orientation, it is clear that speakers (and often researchers) assume some relationship between gender and sexuality. This research has transformed the field of language and gender (*see Gender and Language*) into the field of language, gender, and sexuality (Bucholtz, 2004). Speakers may refer to sexual orientation as a means of performatively asserting gender identity and vice versa.

Cameron (1997) examined the way in which a group of heterosexual male college students use references to homosexuality to convey masculine gender identity. Cameron examined a conversation in which the men discuss 'gay' classmates at length. The most important aspect of Cameron's analysis is the fact that some of the 'gay' classmates are clearly heterosexual (one is described as constantly "hitting on girls"). The men are able to assert a masculine identity by distinguishing themselves from a classmate who they depict as homosexual (and hence effeminate). The actual sexual desires of the 'gay' classmates have little relevance to the interaction, and the discussion of sexual orientation is primarily used to construct

masculine gender identity. Cameron's study demonstrates that linguistic references to sexual identity may be entirely divorced from actual sexual desires or sexual practices (Bucholtz and Hall, 2004).

Studies have also examined the reverse phenomenon, in which gender identity is used as a means of asserting sexual identity. Peebles (2004) examined the language in an ex-gay ministry in the United States. Ex-gays are evangelical Christians who have experienced (or continue to experience) same-sex attraction (and who may have identified as gay or lesbian) but who attempt to transform their sexual identity to that of heterosexuals based on their religious belief that homosexuality is morally wrong. The transformation to a heterosexual identity revolves around negotiating and acquiring new norms for gendered behavior. The ex-gays in Peebles's study view the transformation as one of adopting some aspects of traditional normative gender behavior while questioning other aspects of stereotypical masculine or feminine behavioral norms (including norms for language use). Peebles's research demonstrated the inverse of Cameron's study, showing that sexual identity may be expressed through markers of gender identity.

Conclusion

The field of language and sexuality is a very recent phenomenon and its emergence has involved much debate (Bucholtz and Hall, 2004; Campbell-Kibler *et al.*, 2002). The focus on marginalized speakers in queer linguistics has resulted in new perspectives on the ways in which speaker identities are conveyed through language. In particular, the assumption that there are 'gender-exclusive' forms of language (i.e., structures used only by males or only by females) is no longer tenable given this attention to speakers who have generally been classified as 'exceptions' (Hall, 2003). However, much additional research is needed before we can begin to fully understand the relationship between language and sexual and gender identities.

Reading and Multiliteracy

B Street, King's College, London, UK

© 2006 Elsevier Ltd. All rights reserved.

A rich vein of articles and books has recently offered new perspectives on reading and literacy, invoking such terms as 'multiliteracies' and 'multiple literacies.' In this piece, I will signal some of the debates and concepts in this emerging field, with particular reference to New Literacy Studies (NLS), both in terms of theoretical perspectives and of their implications in schooled contexts, as theorists and practitioners address the tensions and possibilities that arise when students and teachers apply such innovations to curricula and classrooms. While 'reading' has generally been seen in educational contexts as about decoding and much of the policy literature follows this line (cf. Snow, 1998), those researching literacy from a social practice perspective offer a broader interpretation of reading as well as of literacy that has profound implications for classroom practice.

Such reconceptualization begins from the problematizing of what counts as literacy at any time and place and asks 'whose literacies' are dominant and whose are marginalized or resistant. This query entails the recognition of multiple literacies, varying according to time and space but also contested in relations of power. To address these issues ethnographically, literacy researchers have focused on 'literacy events' and literacy practices,' the latter representing an attempt to handle the events and the patterns of activity around literacy but to **link** them to something broader of a cultural and social kind: part of that broadening involves attending to the fact that in a literacy event, we have brought to it concepts, social models regarding what the nature of this practice is and that make it work and give it meaning. This reconceptualizing of literacy has produced a wealth of 'ethnographies of literacy' (cf. Street, 1984, 2001; Barton, 2000; Baynham, 2004). The strength and significance of this approach and this considerable literature is attested by a recent spate of critical accounts that have addressed some of the problems that they raise, both in general and, more specifically, for educational applications.

An apt place to begin is with the contestations over the terms 'multiple literacies' and 'multiliteracies.' The notion of multiple literacies was coined in the early 1980s (Street, 1984) in order to make a contrast with a reified autonomous notion that dominated the field at that time, which assumed that there was only one thing called 'literacy' – which had a big 'L' and a little 'y': which was singular and autonomous in the sense that it was a factor that independently had effects on other things. The idea of multiple literacies, then, was an important construct in challenging that autonomous singular literacy: literacies vary according to cultural contexts and uses and what is taught in schools as 'the' literacy is only one variety among many.

The concept of multiliteracies that has been put forward by the 'New London Group' (NLG) (Cope and Kalantzis, 2000) refers not to multiple literacies, associated with different cultures or contexts, but to multiple forms of literacy associated with different channels or modes, such as computer literacy or visual literacy. Kress (1997), a member of the NLG, has criticized the further extensions of multiliteracy into, for instance, political literacy, or emotional literacy, thereby using the term as a metaphor for competence. The NLG are more interested in channels and modes of communication that can be referred to as 'literacies.' For Kress, multiliteracy signals a new world in which the reading and writing practices of literacy are only one part of what people are going to have to learn in order to be 'literate' (Kress and van Leeuwen, 1990). They are going to have to learn to handle the icons and the signs, the Word for Windows package with all its combinations of signs, symbols, boundaries, pictures, words, texts, images, etc. The extreme version of this position is the notion of 'the end of language' – that somehow we are no longer talking about language in its rather traditional notion of grammar, lexicon, and semantics, but rather semiotic systems that cut across reading, writing, speech, into all these other semiotic forms of communication. This collection, then, is what is signaled by the term 'multiliteracies': a rather different approach from that entailed by the 'multiple literacies' view outlined above.

These approaches are currently being debated not only in terms of the boundaries of the concepts but also in terms of broader theoretical and methodological issues. In terms of theory, for instance, Brandt (2002) recently commented on 'the limits of the local' evident, she believes, in the ethnographic approach to multiple literacies. She argues that NLS ought to be more prepared to take account of the relatively 'autonomous' features of literacy without succumbing to the autonomous model with its well-documented flaws: this approach would involve, for instance, recognizing the extent to which literacy does often come to 'local' situations from outside and brings with it both skills and meanings that are larger than the emic perspective favored by NLS can always detect. This recognition, of course, is exactly what many educationalists would argue regarding the relationship between local literacy practices and those of the school. Likewise, Collins and Blot (2002) were concerned that, while NLS has generated a powerful series of ethnographies of literacy, there is a danger of simply piling up more descriptions of local literacies without addressing more general questions of both theory and practice. They proposed the terms 'texts power and identities' as a basis for comparative generalization, building on the descriptive capacity of the lenses offered by NLS to engender a more powerful set of generalizations about the uses and meanings of literacy practices. Those lenses were themselves sharpened by a number of contributors to an edited volume *Situated literacies* (Barton *et al.*, 2000). Gee, for instance, located the situated approach to literacies in relation to broader movements towards a 'social turn' that he sees as a challenge to the behaviorism and individualism that NLS has also pursued. Maybin, in the same volume, also links NLS to wider strands of social-critical work, offering a way of linking Foucauldian notions of Discourse, Bakhtinian notions of intertextuality, and work in Critical Discourse Analysis with the recognition from NLS of "the articulation of different discourses [as] centrally and dynamically interwoven in people's everyday literacy activities." Bartlett and Holland (2002) likewise proposed an expanded conception of the 'space of literacy practices,' drawing upon innovations in the cultural school of psychology, sociocultural history, and social practice theory. They are particularly concerned to harness NLS to broader concerns with identity and suggest three concepts: figured world, artifacts, and identities in practice. As with the other papers and books, they build these extensions and developments upon the basic tenets of NLS, using ethnographic case studies of literacy in practice.

Another update and extension of NLS is to be found in Hornberger's edited volume (2002) in which authors attempt to apply her conception of the 'continua of biliteracy' to actual uses of reading and writing in different multilingual settings: 'biliteracy' is defined as "any and all instances in which communication occurs in two (or more) languages in or around writing" and is described in terms of four nested sets of intersecting continua characterizing the contexts, media, content, and development of biliteracy. A number of the authors, as in the Martin-Jones and Jones (2001) book, drew out the links of NLS to such multilingual settings. Peter Freebody's recent account of the different ways in which 'Critical Literacy' has been construed (Freebody, forthcoming) offered a further, critical perspective on NLS and its implications for education. He argued that the meanings of CL vary according to both "focus and method of study on the one hand and, on the other, the disciplines that have developed these approaches." Thus:

- Linguists have generally taken the text as a semi-otically structured object, to be the prime unit of focus of critical literacy;
- Sociologists have generally focused on how language uses signal as the operation of social formations such as race, gender, and class, and how these formations in turn give shape to how we read, write, look, talk, and listen; and
- Anthropologists have taken cultural practices and the ways that different literate representations variously implicate and afford these.

Being rooted in anthropological approaches, although perhaps recently focused more in ethnographic methods from a range of sources, New Literacy Studies can be seen to focus more on practices than on texts and more on fine-tuned processes of identity construction than on gross categories of class, race, and gender. However, all three approaches would probably agree with Freebody's general characterization of CL as concerned "with giving access to texts, transforming sociopolitical processes and" – most crucially for NLS – "developing the practical understanding that people are educated to become variously the objects and subjects (both the topics of and the readers and writers) of a selected tradition of representing reality in public and official forms." How such traditions are constructed and reproduced and how individuals and social groups are inserted into them is a central focus of NLS – taking nothing for granted with respect to literacy and the social practices with which it becomes associated.

The effects of these critical engagements is that NLS is now going through a productive stage of

theory building that first establishes and consolidates many of the earlier insights and empirical work, and second builds a broader and perhaps less beleaguered field of study that can appeal beyond the specific interests of ethnographers on the one hand and educationalists on the other, to those engaged in more general issues of identity, power, and textuality. The next stage of work in this area, then, is to move beyond simply theoretical critiques of the autonomous model of literacy and to develop positive proposals for interventions in teaching, curriculum, measurement criteria, and teacher education in both the formal and informal sectors, based upon these principles. It will be at this stage that the theoretical perspectives brought together in the 'New Literacy Studies' will face their sternest test: that of their practical applications to mainstream education. In a recent edited volume (Street, 2005), a number of authors took on this challenge and attempted to follow through such practical applications of the NLS approach, in terms of the links between such theoretical debate and the work of teachers in school addressing literacy issues. Likewise, Hull and Schultz (2001) built upon the foundational descriptions of out-of-school literacy events and practices developed within NLS, to return the gaze back to the relations between in and out of school, so that NLS is not seen simply as 'antischolar' or as interested only in small scale literacies of resistance. They want to use the understandings of especially children's emerging experiences with literacy in their own cultural milieus to address broader educational questions about learning of literacy and of switching between the literacy practices required in different contexts. This issue was also addressed in current research by Baker, Street, and others applying literacy theory to the understanding of numeracy practices in and out of school (Baker and Street, 2004; Baynham and Baker, 2002).

Meanwhile, Larson's edited volume (2001) addressed the relationship between current policy initiatives that stress a more decontextualized view of literacy and the approaches indicated here, including NLS and 'critical' perspectives: the authors demonstrated the problems with the dominant narrow approach and attempted to construct more meaningful solutions. This theme was developed further in a volume, *Framing literacies* (2005), in which Larson and Marsh attempted to reconnect what we know about literacy learning to what we do. The book took three prominent theoretical frameworks, New Literacy Studies, Critical Literacy, and Sociocultural Theory, and illustrated what these frameworks look like in real case examples, articulating how the frameworks discussed work together to construct rich and complex contexts for literacy learning and progressive

frameworks for research. Another volume in this genre, edited by Rowsell and Pahl (forthcoming), also attempted to make links explicitly between theory and educational practice. At a theoretical level, they attempted to combine the multiliteracies and the multiple literacies positions: "To meet the demands of our changing communicational landscape, we need to adjust our notion of literacy and its implications on how we produce texts in multiple settings, at different times, by different sets of actors." At the same time, they want to follow through the implications of this production for pedagogy and curriculum, and the authors in their volume provided examples of actual classroom practice where such shifts can be identified. The same two authors (Pahl and Rowsell, 2005) have also written a book for classroom teachers offering a practical guide to applying New Literacy Studies within primary, secondary, and family literacy contexts. It aimed to offer ways to rethink, redefine, and redesign language and literacy in the classroom to meet the contemporary needs and skills of students.

All of these initiatives, then, make considerable demands on both theorists and practitioners in the area of language and education in general and of literacy and reading in particular, challenging dominant views of each term and its applications. From this perspective, reading is now located in the broader field of literacies, and the understanding of literacies is in turn contested between approaches from ethnography, critical theory, and sociocultural views of language and learning. Whichever position one takes in this fast moving field, it will no longer be possible to envisage either reading or literacy in the simple, unidimensional ways that have dominated schooling until now.

Language can be used as a means of communication because (some of) its elements have meaning. But what is 'meaning' and what is communicated? These questions are complex, and have not always been carefully considered in psycholinguistics. Since the late 1970s, however, there has been a growing agreement that one thing – not the only thing – that is communicated is information about situations in a world. Sometimes that world is the real world, as in news broadcasts or conversations about what happened last night. Sometimes it is a fictional world, for example in novels and short stories, and sometimes it is an abstract domain, as in many articles in this encyclopedia. Communication about situations is primarily associated with literal meaning (and knowledge-based inferences from literal meaning), which is considered to be largely compositional. Communication therefore depends on mental representations of situations.

Situations comprise individuals with properties, and relations among those individuals. Some of

those relations make up events, states, and processes (sometimes called, as a class, eventualities). These latter also stand in relations to one another, such as cause and effect. To convey information about situations, it is necessary to convey information about their component parts. To do so, it is necessary to refer to individuals, properties, and eventualities.

Reference is one kind of 'meaning of meaning,' though it is perhaps not the most obvious one. Another kind of meaning is sense, or connotation. The distinction between sense and reference, and the connection between them, was made explicit by the logician Gottlob Frege in the late 19th century. Frege was unimpressed by natural languages, and sought to construct a logically well-behaved language in which he could describe the logical foundations of mathematics. In this *Begriffsschrift* (conceptual notation), meaning is compositional: The meaning of a complex expression is determined by the meanings of its parts and their method of (syntactic) composition. Sense (*Sinn*) corresponds roughly to conceptual content (or mode of presentation, as Frege sometimes put it). Reference (*Bedeutung*) is what an expression stands for (in any possible context of use). 'The morning star' and 'the evening star' are two modes of

presentation of the planet Venus (expressions with different senses). In the real world, the two expressions have the same reference (or referent in more modern English parlance), Venus itself. Ideally, both sense and reference are compositional.

In ordinary language, it is natural to think of noun phrases, such as 'John,' 'the table,' and 'the book I lent you last week,' as expressions that refer to particular people or objects, at least when those expressions are used in appropriate contexts. However, in Frege's view, every expression has a sense and a reference. In particular, sentences have truth values (true or false) as their referents. Mathematical statements are either true or false. In everyday language, the truth of a sentence depends on the context in which it is used. Whether it is true that 'John is tall' depends on which John is being talked about. The other base point of Frege's system is the proper name, in an extended sense. In arithmetic, for example, '2' is a proper name for the number two. Proper names have objects as their referents. In the case of '2,' that object is an abstract object (Frege was a Platonist).

For Frege, and many 20th-century philosophers and logicians inspired by his work, objects (or entities) and truth values are the two basic semantic types. Montague (see Thomason, 1974), for example, who made the first detailed attempt to apply broadly Fregean ideas to natural language, followed Frege on this point. However, it has more recently been suggested (e.g., by Parsons, 1990) that eventualities and properties are basic semantic types (rather than derived types, as Montague and Frege claimed). For example, a property such as 'is an even number' is, for Frege, a function from objects to truth values (it maps 2 to true and 3 to false, for example).

Frege focused on proper names as expressions that refer to objects. What about expressions such as 'the bag,' often referred to as definite descriptions in the philosophical literature? Informally, it is natural to consider such expressions as referring to objects. However, a tradition going back at least to Bertrand Russell considers that definite descriptions are not referring expressions at all, but rather quantifier expressions used to state (in the case of a singular definite description) that there is one and only one entity that has a certain property. Thus, Russell was able to claim that 'the present King of France is bald' is false, if France has no king, because it asserts that France has one and only one present king.

Psychological Issues

The ideas presented so far may seem far removed from psychological considerations. However, if all expressions have (a sense and) a referent, and the

sense and reference of complex expressions can be built up compositionally, word identification plus syntactic analysis can form the basis for semantic interpretation in language comprehension.

As has already been noted, natural languages do not behave like logical languages of the kind Frege studied. In mathematics, '2' always means the number two. In English, 'John' may be John Smith on one occasion and John Brown on another, even in the same text. Likewise, Russell's 'the present King of France' is an atypical definite description. There is only one France, and if a country has a king, it only has one. A more typical definite description, such as 'the cold cup of tea' will have different referents in different contexts (and no referent in many contexts).

Language is used in context. Part of the context, particularly in spoken language, is the nonlinguistic context in which the language is used. Another part is the linguistic context – what has been said or written so far. From a psycholinguistic perspective, what is crucially important is the mental representation of the context, whether linguistic or nonlinguistic, which mediates language understanding. This claim should not be mistaken for the idea that language refers to the mental representation rather than the real world. Rather, the claim is that, from a psychological perspective, language use must be regarded as mediated by mental representations.

Situation Models

Given the idea that language conveys information about situations in the real world, or fictional or abstract worlds, the relevant mental representations must represent those situations. Such representations are called situation models or mental models. Mental models must contain elements corresponding to the basic building blocks of the world (entities, properties, eventualities, truth values, or whatever) and there must be computationally tractable methods for constructing them. A single clause usually presents an eventuality, whose type is determined by the verb. Entities are typically introduced by noun phrases in various syntactic positions and playing various thematic roles. Local 'who did what to whom' information can be constructed compositionally. Relations between eventualities are sometimes indicated explicitly, for example by the use of connectives such as 'but,' 'because,' and 'however.' Sometimes they are implicit and can only be computed by using background knowledge.

Psycholinguists have not paid a great deal of attention to questions about what different types of expression refer to. They have assumed that local 'who did what to whom' information is computed, perhaps

with reference to background knowledge, and then integrated (again perhaps using background knowledge) with other bits of 'who did what to whom' information from elsewhere in the text.

Coordination between Speakers

One issue that has been investigated in psycholinguistics is how speakers coordinate with one another to ensure successful reference. When a speaker talks about an object or a writer writes about one, the addressee must correctly identify the object being talked about if communication is to be successful. In many cases nonverbal context plays a crucial role in such coordination: speaker and addressee are looking at, or handling, the same object, for example, while talking about it. However, not all cases are so straightforward. Johnson-Laird and Garnham (1980) identified some very general considerations that help to determine successful reference, for example whether an addressee will recognize that a particular description (e.g., 'the man I met last night') refers to a particular person. More recent work on dialogue has found that while speakers may not consider the knowledge that they share with their addressee (common ground) when initially planning an utterance (Horton and Keysar, 1996), under normal discourse conditions utterances often ultimately reflect the common ground between an speaker and hearer (Clark, 1996). Furthermore, over successive turns in a dialogue, interlocutors will coordinate the use of different expressions, converging on a single means of referring to a particular object (Garrod and Anderson, 1987).

Anaphoric Reference

Another issue that psycholinguists have looked at in some detail, and perhaps the major question about reference that they have concerned themselves with, is that of second and subsequent reference to the same entity, via pronouns or other anaphoric expressions. One piece of 'who did what to whom' information might be that John sent a letter to Jill and the next piece might be that he hoped she would receive it the next day. To an English-speaking reader it will be obvious that 'he' is John, 'she' is Jill, and 'it' is the letter that John sent to Jill. However, it is not apparent just from the form of the expressions 'John' and 'he' that they refer to the same person and, indeed, in many contexts they would not, for example (1).

- (1) John confessed to Bill because he offered a reduced sentence.

Anaphora is not confined to coreferential noun phrases, though such cases are the most commonly studied in psycholinguistics. As well as identity of reference anaphora, there is identity of sense anaphora, which includes most uses of indefinite pronouns, as in (2), and some uses of definites, for example in 'paycheck' sentences such as (3).

- (2) John has eaten a big bowl of vanilla ice cream and now Judy wants some.
(3) The man who gives his paycheck to his wife is wiser than the man who gives it to his mistress.

Here, 'it' is a paycheck, but not the one that was referred to in the first part of the sentence. Furthermore, not all anaphora is nominal. English, in particular, is rich in verbal anaphors, such as the verb phrase ellipsis in (4).

- (4) I have always wanted to travel to China and next summer I am going to.

Verbal anaphors are typically identity-of-sense anaphors, and many of them are ellipses in the technical sense of Sag and Hankamer (1984): what is elided or replaced by a verbal anaphor must have an exact counterpart in the surrounding, usually preceding, text.

Another issue is that some uses of definite noun phrase anaphors, and in particular pronouns, are analyzed as bound variables, and not as referential expressions, as for example in (5).

- (5) Every dog loves its owner.

However, the parallel between (5) and (6) suggests that they should, perhaps, be treated similarly, which they are in theories such as discourse representation theory (Kamp and Reyle, 1993).

- (6) Fido loves his owner.

Psychological accounts of anaphoric reference are concerned with the mental mechanisms, representations, and processes that underlie the production and comprehension of anaphoric reference. They must be informed by linguistic accounts of how and when different types of anaphoric expression can be appropriately used. However, they must also be subject to empirical tests in psychological studies generating standard types of psychological data. Linguists describe the morphosyntactic properties of anaphoric expressions, such as gender and number marking on definite pronouns, which affect their interpretation. They also describe syntactic constraints on the interpretation of pairs of noun phrases as (possibly) coreferential, for example through the principles of binding theory. At a higher (discourse) level, attempts

have been made to specify constraints on the form that anaphoric noun phrases should take. Some researchers have considered the accessibility or givenness of the antecedent (e.g., Ariel, 1990; Gundel *et al.*, 1993) to account for when particular forms are required or permissible, and we shall return below to other accessibility- or focus-based accounts of the form of referring expressions. Others have considered the discourse function of anaphoric forms in order to account for their use, including the purpose of particular forms, such as the demonstrative 'this X' to refer to antecedents currently out of focus, and overspecific forms (e.g., a proper name when a pronoun would be sufficient for identification) to shift discourse topic (e.g., Vonk *et al.*, 1992).

The most straightforward kind of reference is to people, animals, and objects. It therefore seems likely that reference to such objects is mediated by representations in which those people, animals, and objects are represented. Mental models (or situation models) are representations of this kind. People talk about situations in the real world or in imaginary worlds or abstract domains, and mental models of these situations can be used to guide the selection of referring expressions, and can be constructed and modified in response to the comprehension of referring expressions. There must, therefore, be a set of procedures for generating referring expressions from mental models and for generating and modifying mental models on the basis of referring expressions. In addition, items can be represented in mental models on the basis of perceptual information.

On one view, once an item is represented in a mental model, anaphoric expressions might make direct contact with their representations in comprehension, which need not be tied to the particular linguistic expression used to introduce them. Sag and Hankamer (1984) proposed that definite pronouns and other deep or model-interpretive anaphors worked in just this way. They also proposed that many verbal ellipses were indeed ellipses, and had to be interpreted by effectively copying part of a fairly superficial representation (Logical Form, in their view) of a piece of nearby text. Garnham *et al.* (1995) showed that, at least when a pronoun is fairly close to its antecedent, the linguistic form of the antecedent expression does affect the interpretation of definite pronouns. However, this could be because mental models contain information about how their elements have been or might be referred to. Garnham and Oakhill (1987) have also shown that the interpretation of ellipses can be influenced by an underlying mental model, in a way not allowed for by Sag and Hankamer. Another line of evidence supporting the

idea that anaphoric expressions take their meaning via mental representations of objects rather than linguistic descriptions of those objects comes from the study of indirect reference in which the referent of an anaphor is not explicitly mentioned in previous text, as in (7).

- (7) James tried to write to Alison many times, but always tore them up in the end.

In this case, a previous antecedent trigger ('write'; Cornish, 1999) makes the referent ('letters') available for anaphoric reference ('them') by allowing it to be represented in the mental model of the text. If reference depended on the literal text then such indirect reference would be impossible; however, some researchers have reported it to be relatively common (Yule, 1982).

Perhaps the most important factor in anaphoric reference is focus. As we mentioned earlier, in natural languages, unlike the logical languages studied by Frege and others, the interpretation of referring expressions is often highly context dependent. A simple definite description such as 'the bird' is referentially highly indeterminate out of context, but in a particular text or conversation it can readily be used to refer to a particular individual bird. Because mental models are specific to individual texts, they help to explain this fact. However, in a text of any length an expression such as 'the bird' might refer to different individuals on different occasions, suggesting that mental models are partitioned and that different sets of individuals are more salient at different points in the text. Furthermore, depending on the particular local structure of the text, an individual that could be referred to as 'the bird' might be more appropriately referred to as 'it' or 'Joey' or 'the parrot' or 'the large bird.' Attempts to explain these facts, both from the point of view of production, or selecting appropriate referring expressions, and from the point of view of comprehension, or how difficult certain referring expressions are to interpret in different contexts, are usually discussed in terms of the accessibility, prominence, or focus status (in the psychological, rather than linguistic sense) of the antecedent.

The work of Grosz, Sidner, and others (see especially Grosz and Sidner, 1986) has led to the distinction between global and local focus. Global focus is related to episode structure (Anderson *et al.*, 1983), or more generally to that of discourse segments and their relations to one another. As Sidner (1983) and others have pointed out, in narratives and other texts about people, protagonists are important in determining focus, though Grosz and Sidner subsume such effects under more general principles. Anderson

et al.'s (1983) episode structure effects are linked to the status of protagonists, as is the finding that proper names produce a stronger focusing effect than definite noun phrases.

Local focusing is particularly important in determining which recently mentioned people (or things) would preferentially be referred to pronominally. Centering theory is a theory of local focusing that has been developed within Grosz and Sidner's framework. It is couched as a theory of how attention shifts within a discourse segment. It identifies, within any utterance, a set of forward-looking centers, or things likely to be rereferred to in the upcoming discourse. It also identifies one backward-looking center, which is the current (local) topic, and which should be the same as one of the forward-looking centers of the previous utterance.

Centering theorists have made various attempts to specify when references should be pronominal. An early view, which focused on the idea that the backward-looking center should be pronominalized (particularly if it picks up the highest ranked forward-looking center of the previous utterance), led to a series of experiments by Peter Gordon and his colleagues on the repeated name penalty (Gordon *et al.*, 1993 and later work), a difficulty in comprehension caused by repeating a proper name or a common name rather than using a pronoun. Gordon found empirical evidence for this effect, particularly for anaphors in syntactic subject position, and when there was not a shift of center. However, later versions of centering theory have, on empirical grounds, relaxed the pronominalization rule to say merely that if any of the forward-looking centers of the previous utterance are pronominalized in the current utterance, the backward-looking center of the current utterance must be pronominalized.

A different approach to focusing, and the way it affects anaphoric reference, is found in Amit Almor's (1999) informational load hypothesis (ILH), which is founded more directly in psychological research than is centering theory. The ILH asks: what factors make a particular form of anaphoric reference easy or difficult to process, given the context in which it occurs and, in particular, given what its antecedent is? According to Almor, three factors are important: the focus status of the antecedent, whether the anaphor adds new information about its referent, and the informational load of the antecedent-anaphor pair. From the examples he considers, Almor appears to be investigating local focus, and in his experimental work he focuses items using *wh*- and *it*-clefts, which are thought to mark contrastive focus. Informational load is the crucial new concept in this hypothesis and it is defined in terms of the conceptual distance between

antecedent and anaphor, with conceptual distance taken to be positive when the antecedent is less specific than the anaphor ('... the bird ... the robin ...') and negative when it is more specific ('... the robin ... the bird ...'). Thus, for anaphors that are less specific than their antecedents, informational load decreases (by becoming more negative) as conceptual distance increases. Informational load can be justified if the antecedent is not in focus, as it helps to reactivate the representation of the antecedent. Indeed, previous work by many researchers supports the idea that increased overlap between an antecedent and its category anaphor aids in anaphor resolution, with more typical antecedents (e.g., robin) for a given category (e.g., bird) leading to faster processing times for the anaphor compared to atypical antecedents (e.g., ostrich). However, when the antecedent is in focus the increased information load produced by semantic overlap is not justified. According to Almor, informational load arises because semantic overlap in working memory produces an interference effect, just as phonological overlap does, and this interference competes with the facilitatory effect of semantic overlap just described. Thus, the ILH leads to the surprising prediction of an inverse typicality effect in anaphor resolution for focused antecedents. Since 'ostrich' is conceptually more distant from 'bird' than 'robin' is, the pair '... the ostrich ... the bird ...' has a lower (more negative) informational load than '... the robin ... the bird ...', and the former pair should be easier to process. With clefted antecedents, Almor reports this result.

In our own lab we have failed to replicate this result consistently with a typicality manipulation, though we have shown it in a category hierarchy, where the conceptual distances are clearer ('... the cobra ... the reptile ...' is easier than '... the snake ... the reptile ...'). However, we have been unable to find evidence for semantic interference in working memory.

In describing the ILH, Almor does not discuss the effect of multiple possible antecedents for an anaphor. However, potential antecedents that turn out not to be antecedents ('Phil' in [8], for example) affect anaphor resolution.

- (8) Jack threw a snowball at Phil, but he missed.

Gernsbacher (1989) showed that once an anaphor was resolved, the nonantecedents were suppressed, and that, for pronouns at least, this process took some time. Garrod *et al.* (1994), however, suggested that pronouns could be resolved immediately if they referred unambiguously to focused main characters.

The ILH tries to provide an integrated account of the ease of processing of noun phrase anaphors

of various types. In this respect it differs from previous work, which has tended to produce lists of (apparently independent) factors that affect the ease of interpreting anaphoric reference. One such factor is the distance between a noun phrase anaphor and its antecedent, which is particularly important in the case of pronouns. However, it is likely that foreground or focus interacts strongly with this factor, since material intervening between a pronoun and its antecedent is likely to shift the focus away from the antecedent. A related issue is the interaction of distance and working memory, or how near is 'near'? Ed O'Brien (e.g., 1987) has emphasized the need to distinguish between potential antecedents that are still likely to be represented in working memory and those that are not.

Another factor that has been investigated in the case of pronoun resolution in particular is implicit causality. When a pronoun occurs in a statement of an explicit cause following the description of an interpersonal event, the interpretation of the pronoun can depend on the verb used to describe the interpersonal event. For example, in (9) 'he' is likely (though not certain) to be taken to refer to Bill, whereas in (10) it is likely to refer to John.

(9) John blamed Bill because he...

(10) John called Bill because he...

Garnham *et al.* (1996) suggested that this effect might be a focusing effect, but found no evidence in favor of this view. Rather, it appears, in the comprehension of a completed sentence, to reflect how easy it is to integrate the information in the 'because' clause with the information in the main clause. Thus, a complete sentence such as (11) is easier to process than a sentence such as (12).

(11) John blamed Bill because he had been careless.

(12) John blamed Bill because he needed a scapegoat.

Implicit causality effects may be an example of the use of world knowledge in the interpretation of pronouns, as indeed may the more general effect of the coherence relations between clauses or sentences, which as we mentioned above are often signaled by connectives, on anaphor resolution.

Other factors that have been found to influence anaphor interpretation are more formal, and are possibly used as fallback strategies when content-based strategies fail. These strategies include parallel function (taking the referent of an anaphor to be the item in the preceding clause that plays the same grammatical role as the anaphor in its clause), and preference for syntactic subjects or first-mentioned items in preceding clauses as antecedents for anaphors in the

current clause (though preferences for syntactic objects have also been reported, often depending on the prosodic stress given to the anaphor). Parallel function effects are strongest when the syntactic parallelism between the clauses is strongest. They are interesting because they are difficult to accommodate in both centering theory and Almor's ILH.

The strongest evidence for an overall preference for (unaccented) pronouns to be taken as referring back to an antecedent when it has been mentioned first compared to other possible antecedents comes from probe word tasks (Gernsbacher and Hargreaves, 1988). However, there is evidence that this preference may be an artifact of the testing procedure.

While these factors have been proposed independently of more general theories such as centering theory and the ILH, many of them could be taken up under the notion of focus within these theories. For example, centering theory proposes that an utterance's forward-looking centers are partially ordered to reflect which ones are most likely to be referred to again. This ordering may be based on factors such as syntactic position (indeed, the highest ranked forward-looking center has often been assumed to be the grammatical subject of the sentence). In the ILH, such factors also affect focusing.

Finally, it should be noted that while syntactic considerations undoubtedly influence reference, the reverse can also be true: there is evidence that syntactic processing is influenced by referential considerations. In a story about two women, the noun phrase 'the woman' is likely to be referentially indeterminate. So, although a 'that' clause is preferentially interpreted as a complement clause rather than a relative clause, if a postmodifier is needed to disambiguate a reference, this preference may be overridden, even in initial parsing (Altmann *et al.*, 1992).

Summary and Conclusions

A psycholinguistic perspective on reference focuses on the mental representations and processes that underlie people's ability to use language, both as speakers and writers and as listeners and readers. Mental representations mediate references to things in real, imaginary, and abstract worlds. Linguistic and philosophical analyses bring to light some of the complexities that psychological theories must take account of.

A major concern within psycholinguistics has been to explain second and subsequent anaphoric references to the same person or thing. A variety of factors have been identified as influencing this process, and more recently the more unified approaches of centering theory and the informational load hypothesis have been suggested. These approaches are best

located within a mental models framework that stresses the importance of representations of situations in the world as mediating language processing.

Frege's Legacy

Classical theories of reference assume a strong connection between a sign, its meaning, and its reference. A word connected to a particular object embodies a description containing a rundown of the object's properties. This is to say that a word possesses the capacity to evoke in the mind a cluster of properties that serve to specify the nature of the object to which the word refers. Knowing the meaning of a sign is knowing how it refers, and knowing how it refers is presumably knowing truth – all of which can easily land one in a vicious circle.

Gottlob Frege simplified this formula. He drew a distinction between 'sense' (*Sinn*) and 'reference' (*Bedeutung*). Sense is grasped when a sign is understood, and this sense determines its reference. Frege is often regarded as the prime initiator of 'logicism' – the wedding of logic and mathematics, with the former hopefully becoming the patriarchal repository of all thought and the latter the queen of the sciences. This grand project called for a divorce of signs in general and most particularly of arithmetical signs from 'psychologism.' The idea was to purify language, to rescue it from the swamp of semantic muck into which it had presumably wandered, and to use it against itself in elevating it to clarity and precision. According to Frege and all kindred thinkers, if language could be liberated once and for all time from vagueness, ambiguity, and sticky generalities, it could become a respectable instrument of unequivocal thought. It could be used to paint a faithful 'picture' of any and all meaningful states of affairs. In other words, by 'logicizing' language, its weaknesses could be strengthened, its blemishes could be erased, and future mistakes could be avoided. From the Olympian reaches of the highest rooftops, the world could eventually be seen from a detached God's eye view.

So, the task Frege set for himself by way of this 'sense/reference' distinction was monumental: to establish a method for determining linkages between the objective world and its representation in signs. Equality of meaning of different signs referring to the same object became the watchword. The dilemma was that Frege's grand game plan involved rendering two virtually incompatible domains virtually equivalent: language, on the one hand, and the furniture of the world, on the other. Frege argued that, although two signs with the same reference – *Venus*,

for example – could have two senses (the 'morning star' and the 'evening star'), two signs with the same sense could not enjoy the luxury of different reference.

By way of definitions, the 'intension' (sense) of a sign consists of the conception of the sign, irrespective of that to which it refers. 'Extension' (reference) consists of the things to which that conception refers. Intension used in this context must be distinguished from 'intentionality,' a phenomenological term entailing the property of consciousness whereby it refers to or intends an object. The intensional object is not necessarily existent, but can be merely what the mental act is about, whereas extension presumably involves the 'real' furniture of the objective world.

Thus, 'Venus is Venus' is a tautology. In contrast, 'That star up there in the dark expanse is Venus' is not. It bears reference, extension. 'The evening star is Venus' has both reference and sense, intension. However, 'The morning star is Venus' also sports reference and sense. Reference is one ('Venus'), but sense is two ('evening star,' and 'morning star'). Yet, Frege assured us that no problem exists inasmuch as we specify 'reference' to objects in the physical world, so it is still smooth sailing toward clear and distinct thinking and meaning. Apparently, the relations between Frege's signs and the world are not characterized by symmetry, but by asymmetry. However, this problem was in a manner of speaking pushed under the rug, for the sign's intension (sense) was highlighted somewhat at the expense of extension (reference), and language itself, that apparently ubiquitous partner to mind, held the trump card. This outcome is what we might have expected, since Frege stacked the deck from the beginning.

More questions arise: do sentences impart any information regarding their presumed objects of reference (*Venus*, *morning star*, *evening star*), or simply about the signs themselves ('Venus,' 'morning star,' 'evening star')? If the latter is the case, then why do we like to be comforted by the soothing idea that 'reference' is fixed while meanings may suffer alterations? If meanings change, how can signs actually 'refer to' the same things in the world? If signs do not necessarily refer to the same things but to variable 'semiotic entities,' then do the 'real' things of the world actually make much difference regarding meaning? Can meanings be something found in things referred to, or are meanings embodied within their respective signs? Or in the final analysis, do words hook onto worlds?

The dilemma coiled within Frege's project soon became obvious. No real feeling and thinking mortal could expect to survive in the Fregean desiccated

world that afforded absolute purity of expression. If all fuzzy edges could somehow be smoothed for all time, then eventually even the artist's brush would run dry, the musical score would contain no notes, the dance troupe would be paralyzed, the poet would be condemned to silence and the blank page, and science would find itself suffering from interminable catatonia.

Actually, the demarcation between Frege's 'object' and 'reference' is quite tenuous. It seems safe to say that the idea of 'reference' is not coterminous with the percept and concept of a 'referent.' More adequately stated, it entails the act of referring, or better, the act of interrelating. Once the act has occurred, an 'object' then bounds onto the scene, which is now the incorporation of what is in the Fregean tradition called the sign's 'reference.'

Referential Paradise Lost?

In addition to Bertrand Russell's critique of Frege, Willard V. O. Quine upended the Fregean dream of clear and distinct reference with his 'inscrutability of reference' thesis. Quine *qua* lay physicist conceded that, in point of epistemological footing, physical and mental objects differ only in degree: Both interact with our general conception of things as cultural posits (1953). Yet, he placed greater stock in physical objects than he did in, say, Homer's gods. Physical objects are epistemologically superior to purely mental constructs insofar as they have in the past proved more efficacious as a device for ordering the flux of experience. Lest our confidence run rampant, however, we are reminded that physicalism provides us with no guarantee.

Quine argued that not only does sense not determine reference but that sense is itself indeterminate, as is reference. In his classical example, a field linguist overhears "Gavagai!" from the mouth of a native informant when a rabbit is sighted scurrying through the bushes, and the linguist cannot know whether the word means 'rabbit,' 'undetached rabbit parts,' or 'a rabbit space-time stage.' Because each of these phrases has different extensions, reference to 'Gavagai!' remains radically indeterminate. If this holds true of someone else's language, it is also true of one's own language when one is conversing with a fellow language user. How is one to know if the other person is using her words in the same manner one would be prone to use them? Quine's elaborate argument leads to the conclusion that we must give up the idea that we can refer determinately to that of which we think we speak. However, we are left with a queasy feeling. Quine wrote quite convincingly about the indeterminacy of reference; however, he did so by talking about 'rabbit,' 'rabbit parts,' and

'rabbit stages' as if his words enjoyed some sort of reference or other. Indeed, the very assumption that we cannot refer determinately to the furniture of our world presupposes that we can somehow refer by the fact of our talking about the furniture of our world when claiming we cannot refer to the furniture of our world. In a manner of putting it, the indeterminacy of reference cannot be said, yet we can apparently say it.

What is Quine's solution? Bite the bullet and concede that the very idea of reference is meaningless. Saving grace can be had, Quine has told us, if we have a background language against which to gauge the meanings of the words in the target language. The sentence, "Gavagai!" refers to rabbit in what sense of 'rabbit?' kick-starts a regress, and we need a background language as a fulcrum point to regress into so that the regress will not continue unabated. The background language gives words in the target language sense, if only relative sense: sense relative to the background language. Demanding determinate reference would be like quantum physics demanding *both* determinate position *and* velocity, rather than *either* position *or* velocity relative to a given frame of reference – the background language. So, we acquiesce to our mother tongue, take words at face value, and do the best we can with what we have.

Yet, why, we might ask, should we have faith in our mother tongue?

A Retreat into Imaginary Worlds and Language in Search of an Answer

Historically, extension has been supposedly upfront and stalwart, intension uncertain and anemic. However, Quine claimed that both are inscrutable. Of course, within the parochial confines of our own language, extension continues to seem more reliable than intension. However, this is not necessarily so: The empirical determinacy of extension, through time, cannot even be guaranteed within our own language. Thus for Quine, and, more recently from another vantage point, that of Jacques Derrida (1973), there is no experience that can provide data with which a statement can be absolutely verified. There are no data, because there is no absolute 'immediacy' or 'presence.' This lack renders the meaning of the most basic of statements such as "That raven is black" simply undecidable, for such statements do not refer instantaneously to some independent empirical entity in the 'real' world. We can do no more than gather up an unruly collection of unfixed meanings and muddle along. Reference is ultimately imaginary, or at most it is a linguistic act.

Most Fregeans of a positivist bent contended that, regarding imaginary constructs or fictions,

there can be no meaningful concern for reference or truth. Recently, a new generation of language philosophers and literary theorists has undertaken the analysis of reference in fiction; their efforts often have been governed by contrived explanations of the difference between normal reference and the presumably aberrant, abnormal practice of reference to non-existent objects. Literary theorist Thomas Pavel (1986), for example, argued that there *is* reference to fictional worlds, whether the 'objects' contained within them exist in the 'real' world or not and whether they are possible or impossible 'objects.' He brandished his idea that normal and marginal referential practices are different in degree rather than in kind because they display many identical characteristics: Fictional reference is by no means a logically strange activity, but rather is a close cousin to our conventional manner of making reference. Although at one point Pavel admitted to a 'complex and unstable' relationship between texts and worlds and between the 'real' world and fictional worlds, he suggested a deep-seated, tacit human assent toward 'textual realism'; this is rooted in our very nature to the degree that we tend to compensate for the lack of referential immediacy "by the strength of our ontological commitments," for we confidently "regard our worlds as unified and coherent, our fits of ontological prodigality notwithstanding" (Pavel, 1986: 73).

The notion of imaginary or fictive reference as a linguistic act tends to historicize reference, to render it a matter of language conventions: How we use our words determines that to which they refer. This is also to assume that extension enjoys no necessary priority over intension. Richard Rorty (1982) also historicized reference. Our ancestors, he wrote, believed in many things that do not really exist – they are purely intensional objects the likes of which we label 'unicorns,' 'werewolves,' 'mermaids,' and such. Ordinarily, we tend patronizingly to dismiss these hapless predecessors; they were steeped in prejudice and superstition. Century after century, they failed to name the 'real,' whereas we somehow would like to believe we are finally getting things right. However, Rorty argued that the traditional notion of reference provides no axiom by means of which to solve the problem of our ancestors invariably being wrong while we are largely right. On so doing he referred to three senses of 'refer.'

Hilary Putnam's (1990) 'opaque' A-reference is commonsensical: It involves things we refer to not by 'metaphysical realism' but by the very act of thinking we are referring to them (including nonexistent entities), which is what Putnam termed 'internal realism.' 'Transparent' B-reference is of the Bertrand Russell type in the sense that only what exists can

be referred to, the technical use of the term generally being limited to linguistics and philosophy (or, in Putnam's words, 'metaphysical realism'). C-reference entails something like what Thomas Pavel (1986) called 'mixed sentences.' The statement, 'Jove's thunderbolts are actually electrical discharges from the clouds,' includes both our misguided ancestor's A-reference ('Those are Jove's thunderbolts') and our own enlightened and presumably superior B-reference ('Those are nothing but electrical discharges from the clouds'). The question Rorty asked is: How was perennial ancestral error suddenly seen as error by means of its alteration to produce an apparent truth? The best we can do is to assume our ancestors did the best they could, expect the same of ourselves, and trust our descendants will do likewise.

If we apply Rorty's notion to the idea of fictive worlds and their interpretation by successive communities of literary addicts, we might surmise that the *Don Quixote* our ancestors read 'referred' to a relatively limited fictive space, the borders of which were expanded with subsequent readings by future readers. Consequently, our *Don Quixote* world is exceedingly vast in comparison with that of our ancestors. In this vein, previous readings of Cervantes's masterpiece actualized a certain part of the potential representing the novel's fictional universe, whereas current readings are capable of actualizing a greater portion. But are they? Our ancestors' form of life had myriad facets, many of which are not known to us or are simply no longer accessible to us. Of course, our readings are contextualized within the numbing complexity of our contemporary milieu, in addition to our awareness of intertextual implications. Yet, our ancestors had their own access to the intricately woven fabric of their oral tradition, as well as the literary works of their day, some of which we have relegated to the attic. Do not readings separated by vast expenses of space and time become radically distinct? Can there be a set of criteria for determining the magnitude of textual fictive space?

In view of these difficulties in conceptualizing an ontological framework for fictions, one might tend to concur with Rorty that over the long haul reference is pointless. All we need is the common sense notion of 'talking about' – A-reference – according to which the criterion for what a statement is 'about' is, in varying degrees of approximation, whatever we think we are talking 'about.'

Our Fallible Limitations

Yet, perhaps Rorty's commonsensical talking 'about' some-*thing* and therefore merely talking and

somehow getting along swimmingly is tantamount to Pavel's counsel that we minimize indeterminacy of reference and the incompleteness of all worlds by gracefully acknowledging their complexity and risking "the invention of a completeness-determinacy myth." The example of *Don Quixote* is once again evoked. Our venerable Hidalgo reads the world around him according to novels of chivalry, regardless of empirical evidence disproving his hypothetical framework. However, in a sense his hypothesis is correct. After all, he manages to succeed "in the detailed construction of a coherent, if precarious and incomplete, world version" (Pavel, 1986: 111).

Granted, Cervantes's hero packed his universe into the Procrustean bed of 16th-century prose. In so doing, he read fiction as if it referred to the real, serving as a warning to all readers, whether they are engaged in reading the text of the universe or the universe of texts. A certain 'referential fallacy' surfaces here. Regarding our present-world version as the field of reference, which we would by and large like to take as 'real,' there is no guarantee that we somehow got things right. Therefore, if in the sense of Karl Popper (1963), confirmation is inevitably failed refutation, we must go on being wrong with the idea that in the long run somehow we will be able to succeed. Regarding our textual worlds offering up their points of reference to us, which we take to be fictions and 'irreal' and perhaps at their best 'real' by proxy, no matter how complete our interpretation may take us, there will always be some way to take it a mite further. Either way, pinning our words and signs onto whatever imaginary or physical world or worlds lie before us is at worst inconsistent and at best it remains an incomplete project. This 'referential fallacy' is not of the Umberto Eco (1976) sort (for a critique of Eco's argument against the notion of reference, see Ponzio, 1993; Knuuttila, 2003).

Alternatives Emerge

In a last-ditch effort to salvage the idea of reference, we have the 'causal theory,' which at the same time delivers a death certificate to any and all attempts to derive reference from a description of the object of a word's properties or attributes.

The causal theory says words, and all signs for that matter, refer to the furniture of the world in terms of historically determined causal chains involving that furniture and our linguistic – and general semiotic – representations of them. This theory demands nothing less than the condition by means of which one part of the world is semantically related to another part. This is a tall order indeed, and it can

place us in a quandary. How many possible causal chains are there for a particular sign and its representation? One culture's, and even one person's, causal chain is another culture's or person's falsity, absurdity, nonsense, or merely silliness. What a causal theory needs is a corollary of counterfactuality; a causal theory must specify reference in conditional terms: What would be the case were certain causal relations to inhere?

Now enter Donald Davidson (1990). Davidson tossed 'reference' into the trash bin of misused concepts. He would like to convince us that reference, whether intensionally or causally construed, cannot support the entire conceptual weight of a theory of interpretation. He alluded to Alfred Tarski's (1956) theory of truth, the paradigm case for which is his T-sentence: "Snow is white" if and only if snow is white.' The Tarskian assumption has it that truth is explicable in terms of reference. With respect to the T-sentence, truth is determined by inspection of the object of reference; truth is explicable in terms of reference.

However, Davidson, in disagreement with Tarski, had no use for such a correspondence theory of truth. He abandoned reference altogether, but held tight to the idea of truth. Availing himself of the 'Principle of Charity,' he argued that truth for one human speaker and truth for another human speaker will always have enough in common for them to find common ground and so they will be able to communicate. Truth, in other words, is a matter of belief, and belief is somehow dependent on the nature of the world. Since the world is a certain way, one speaker cannot interpret another speaker as believing that the world is any way other than the way it is. This is to imply, it would seem, that a human language is a language only on the premise that it can be translated into – and thus interpreted by – another human language. Translation is tantamount to interpretation, and interpretation arises out of beliefs regarding what is true and what is not true, regardless of what might be taken as reference. Fortunately for us, human speakers in the Davidsonian theory will be more rational than irrational, more logical than illogical with respect to their beliefs about the world.

All this is to take the furniture of the world as not some fixed collection of things out there that are waiting for words properly to be slapped onto them. Yet, speakers usually take the world, their world, for what it is, as if it were quite fixed. Davidsonian theory also takes human speakers as generally correct, and any error or disagreement is dependent upon their general correctness. The problem is that error and with it disagreement are not merely possible but actual, for whatever is known of the world is

incomplete, and if presumably complete, then it will often be inconsistent. However, there will always be alternatives from which we stand to learn something more.

This brings us once again to Putnam. Putnam's meaning is neither in the mind, nor the sign, nor the conduit of information flow between signs and speakers and speakers, nor in the thing to which the sign presumably refers. There is no God's eye view of a fixed world replete with mind-independent objects, acts, and events. Signs do not by their nature hook onto things; neither do they correspond to things. Neither does mind create the hooks or establish the correspondence. Rather, "The mind and the world jointly make up the mind and the world" (Putnam, 1981: 55). If we can speak of reference at all, it is reference with respect to the interdependent, interrelated interaction among mind, sign, and world, within the whole of all contexts, both actual and possible, and past, present, and expected in the future. We must take the world, our world, as objective ('external,' 'real,' 'mind-independent'), for it is the only world we have for the moment; yet, we must acknowledge that it could always be taken for something slightly to radically different, so it is 'ideal' ('internal,' 'mind-dependent'). Now, how can we hope to integrate this assertion with the notion of reference?

Reference within the Triadic Concept of the Sign: Peirce

Frege's 'sense' embraced the notion of understanding, and understanding a language cannot be divorced from knowledge. So a theory of knowledge would seem to be in question. In this manner, a theory of sense should be a component of a general theory of knowledge, and knowledge in this respect should involve the idea of 'truth.'

This is not entirely the case, however. The Fregean reference of a name implies the bearer of that name, the object. To know 'reference' is to know the object, but not necessarily to know the 'truth' of the object. Knowledge of objects, acts, and events is not tantamount to knowledge of the 'truth' of those objects, acts, and events. It is, rather, knowledge of the linguistic use of words that interrelate with those objects, acts, and events. 'Sense,' it would seem to follow, is a matter of understanding how those words are used. This linguistic manner of distinguishing between sense and reference serves to liberate us from a psychological interpretation of meaning and from worry about the ontological status of sense and the objects, acts, and events of reference.

Then, do sense and reference give us a way of recognizing or identifying objects, acts, and events

as the bearers of sense and reference? If that is the case, then where are interpretation and understanding: in those very objects, acts, and events; in the words or signs used; in sense and reference; or in the medium carrying those words? Obviously, Frege discarded psychologism, so interpretation and understanding are not in the head. He also had little need for ontology, so they are not in the objects, acts, and events. Neither are they exclusively within the words or signs nor in the communicative meaning (marks on pages or sound patterns in the air). Interpretation and understanding come about within the sentential context; 'The morning star,' 'The evening star,' for example (McDowell, 1993). Yet, such understanding involves words and things; it is basically a dyadic affair, as are the majority of the theories of reference that have popped up since Frege.

That much said, briefly consider Charles S. Peirce's concept of the sign, which is indelibly triadic. Peirce's sign consists of a 'Representamen' (akin to what usually goes by the name 'sign'), an 'Object' (a 'semiotic entity' as some physical object, act, or event is perceived, conceived, or imagined), and an 'Interpretant' (roughly comparable to the interpretation or meaning of the sign emerging from Frege's 'sense'). However, in the Peircean sense an Interpretant, once at least tentatively understood, can then become a sign in its own right. The same can be said for the Object as it is 'semiotically' perceived, conceived, or imagined by some interpreting agent. In this manner, neither reference nor meaning is fixed, for signs are processual.

Thus, **Figure 1** depicts a three-dimensional tripod, not a triangle. The tripod illustrates that each sign component interrelates with its pair of companions in the same way they interrelate with each other and with it. Where are reference and the referent located? The question reveals the problem. There is no location. There is only interdependent, interrelated, interactive triadicity. So, where do sense, meaning,

Figure 1 Peirce's conception of the three-dimensional tripod sign.

interpretation, and understanding take place? Once again, there is a problem with language. They do not 'take place,' for there is no specifiable 'place.' Interpretation, meaning, and understanding are not in the head; the signs; the objects, acts, and events; or in the communicative medium. They are in the entire context, which includes body and mind (*bodymind*) of the semiotic subject or agent. Moreover, they are always becoming something other than what they were becoming – this feature puts them within the now gently flowing, now undulating, now bucking and unruly semiotic stream of Peirce's process philosophy.

How can one account for this apparently disorderly universe of reference and meaning making? In the first place, understanding a language and other sign uses, sense and reference, and meaning making does not necessarily entail explicit knowledge of some theory. The knowing semiotic agent implicitly knows how to make meaning with the tacit assumption that sense and reference are somehow in the meaning making and so gets on with the task with no further ado. There is hardly any demand for describing and explaining what is done. It is just done because the semiotic agent knows what to do and does it. At the same time, because the agent does not ordinarily use nor needs to use some hard-rock theory, rules for doing what she does cannot help but suffer virtually imperceptible to radical jerks, shifts, and upheavals along the way. Thus, what she does is processual and ever changing. Everything changes in her semiotic world except change itself. How so?

Unstable Semiotically Engendered Worlds

Figure 2 gives us the sign or Representamen as either (1) a model of the H₂O molecule in a high-school chemistry class, (2) a mannequin in front of a class for the purpose of studying human anatomy, or (3) a dinosaur model before a group of fifth-grade students. The respective objects – and presumably, the means of reference and the referents – of the signs are (1) unempirical in the unaided concrete sense, yet theoretically existent; (2) empirical, and shared by the entire class; and (3) unempirical, and nonexistent in the present, yet theoretically empirical with respect to human observers in the past.

The teacher in each case has the task of rendering the sign meaningful in terms of some referent, whether unseeable without elaborate equipment, evident to the senses, or presumably seeable by some semiotic agent living in the remote past. To complete this task, she must become a sign, because her students interpret her while they interpret her words and her assortment of extralinguistic signs. At the same time, each student and the collective body of students become signs, because she interprets them through the array of nonverbal cues, questions, and comments she receives from them. In this broader, more inclusive sense, the original signs (1), (2), and (3) become semiotic Objects while the teacher and students become Representamens and Interpretants for one another. So we have two tripods, with the inclusion of the sign makers and sign takers. Put in another

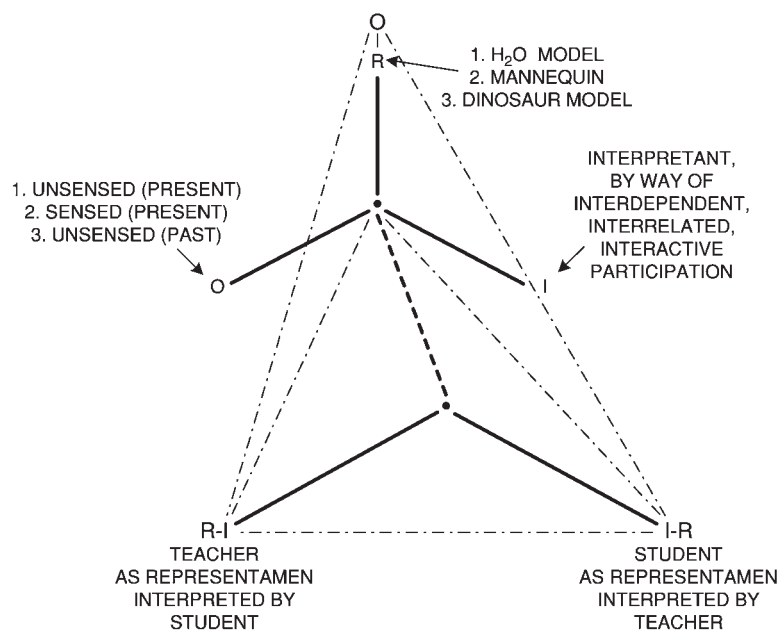

Figure 2 The sign or Representamen given three different ways, creating a 'tripodulation.'

way, we have a 'tripodulation' of what Donald Davidson (1990) called 'triangulation' in the process of bringing semiotic agents into the equation (Pagin, 2001). The upshot is that reference and referents are of hardly any account if we simply consider meaning to reside exclusively in the word, the sentence, or the entire text. Reference, referents, interpretations, meanings, and understanding are holistic affairs. They require entire contexts. There is no clear-cut demarcation between time and place here. Everything, everywhere, in the past, the present, and the future, to a greater or lesser degree come into play.

This is to say that signs, reference, referents, interpretations, meanings, and understanding, as well as the agents of understanding, are all involved in a co-participatory process. The participatory semiotic universe entails interdependence, interrelatedness, and interaction in the widest sense. It is much like one of physicist John Archibald Wheeler's examples illustrating his notion of what he calls the 'participatory universe.' Wheeler offered the example of three baseball umpires (1980). One says, "I sees 'em the way they are" (a naive realist or referential causality theorist). Another rebuts, "I says 'em the way I sees 'em" (a perspectivist, who believes sense determines reference). The third umpire, somewhat more cautiously observes, "They ain't nothing 'til I sees 'em" (a process philosopher coparticipating with signs and their meanings). Our third umpire will have no truck with anything less than the inclusion of herself, ecologically, within the whole of what is becoming (as illustrated in **Figure 2**). As she becomes, so also everything becomes; everything is always in the process of becoming something other. Indeed, "reference is rather a process than an entity, something that needs to be accomplished every time anew" (Knuuttila, 2003: 109).

Reference is always there, for the making and taking, like all signs. For, the semiotic object, like the semiotic agent herself, is nothing more and nothing less than a sign among signs.

Reflexivity

M Silverstein, University of Chicago, Chicago, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Reflexivity is a term variously applied to certain properties of the grammatical systems and lexical forms of language, to the meanings of such forms, to the mental or cognitive capacities of language users, to the textually formed discourses that users create, to states of agentive consciousness of people acting in social situations, and to the special case of researchers as agents seeking to understand social behaviors such as the use of language in society.

Reflexivity as a grammatical phenomenon indicates the referential identity or equivalence of two grammatical terms, generally propositional arguments, of a clause-sized grammatical phrase. The prototype is the relationship of grammatical subject to grammatical object, revealed in English *-self* reflexive pronouns, but indirect reflexives (Takelma), reflexive possessors of nominals (Slavic languages), cross-clause reflexives (Inuit), etc., also are found.

Reflexivity is a lexical phenomenon, in that certain words of a metalinguistic sort, terms denoting or describing phenomena in language itself, are examples in the real world of the very phenomenon. Conceptualizing metalinguistic reflexivity, some logicians devised a special terminological contrast, (German) *autologisch* (English: *autological*, also *homological*) vs. *heterologisch* (*heterological*) for a logical predicate, particularly an adjective, denoting a property true of the metalinguistic form itself; hence English *short* is a (relatively) short word form of one syllable, and autological, while *long*, of similar form, is heterological. A large number of the Indian grammatical terms for describing derivational phenomena of Sanskrit, now applied more widely as standard technical terms, are themselves examples of the phenomenon denoted, e.g., *tat* + *puruṣa-* (literally, 'that'+ 'man') denotes the class of compound stems

composed of modifier (here, the stem of a third person anaphor) plus modified; thus *tatpuruṣa-* is itself a *tatpuruṣa* compound (meaning 'that-(person's)-man').

Reflexivity is, as well, a fact of denotational usage. Among the grammatical and lexical categories of languages, the token-reflexives, or shifters (*see Deixis and Anaphora: Pragmatic Approaches*), or indexical-denotational forms, are pervasive and universal. Most obviously, these include the paradigms of personal deictics such as French singulars *je/moi/melmon* and *tultoil/tel ton*, the referents of which can be located only when one can identify the individual who is communicating with the instance, or 'token,' of the form, and the individual to whom the instance or token has been directed. The reference of such forms reflexively depends on the actual role inhabitation in the communicative event in which a token is used. Not only nominal – functionally referential – but pervasive verbal – hence, predication – categories show token reflexivity of this sort; rules of token-reflexivity underlie the language structure and its anchoring to specific contexts of communication as experienceable events.

Reflexivity, for some writers, also means having a conceptual capacity to communicate token-reflexively, that is, having a metacommunicative intentionality, whether conscious or, to varying degrees, unconscious. Deploying token-reflexivity in respect of community or group norms for communicating, so that language use is appropriate to particular contextual conditions and effective in bringing about contextual conditions, presumes such a reflexive, or 'metapragmatic,' level of cognition (*see Metapragmatics*). This is most transparently revealed in explicit primary performative utterances, where reflexively used forms (such as the Kiksht (Wasco-Wishram) metapragmatic verb/root -pgna- in *yamupgna* 'diálax' 'I-name/pronounce-you 'Diálax.') token-reflexively describes as true of the event in which it is used, the effective (i.e., causally consequential and successful)

act of which the very utterance of the formula with its token consists. Such possibly performative effects of any utterance whatsoever – as much constructing as construing the world-as-denoted – are a constant concern of reflexive constructivism as an epistemological stance.

In the study of cultural texts, e.g., in literary and media criticism, reflexivity is the quality of signaling a metapragmatic relationship of a text to its genre conventions and intertextual field of comparison. An art work thematically depicting ‘doing art’; advertisements that quote or spoof other advertisements or that imply with a wink that addressees know this is one; a film that sets up a scene that is diagrammatically like a famous earlier one, etc. – these all show textual reflexivity, and, by interpretative inference, reveal that the communicators – senders and receivers – too, probably have the metapragmatic agentive consciousness to formulate and understand the reflexive message.

Reflexivity is, increasingly, becoming an important concept in research methodology in the social and behavioral sciences, as well as in contemporary humanistic fields. Originally seen as merely a source of potential bias or error against which positivist social and behavioral science had to struggle, we now recognize the researcher’s own reflexive metapragmatic consciousness and inevitable actual participant status in any contexts of research on humans. This makes all research a dialectical process of moving,

reflexively, back and forth between ‘objective’ and inductive accounts of data in a research context, on the one hand, and on the other, a metapragmatic analysis of the communicative situation in which such data arise to and for the researcher.

Register: Overview

Introduction

Native speakers of a language choose among different words and grammatical structures depending on the communicative situation. For example, we do not use the same words and structures to write an academic term paper that we would use when talking to a close friend about weekend plans.

Researchers study the language used in a particular situation under the rubric of ‘register.’ ‘Register’ is used here as a cover term for any language variety defined by its situational characteristics, including the speaker’s purpose, the relationship between speaker and hearer, and the production circumstances.

Speech and writing can be considered as two very general registers. The most obvious difference between the two is the physical mode of production. In addition, spoken discourse is often interactive and speakers often do not plan their language ahead of time. In contrast, written discourse is usually not interactive. In fact, writers are usually addressing a large audience, rather than a single reader. However, writers can plan and revise the text as much as they want. The final written text includes only the revised and edited language (*see Pragmatics of Reading*).

At the same time, there are many more specified spoken registers. For example, a formal lecture is very different from conversation: it is carefully planned ahead of time, it is addressed to a large audience, it will probably not be interactive, and the speaker will usually want to communicate information about the world rather than telling us a lot about him- or herself. Similarly, there are many specific written

registers. For example, e-mail messages are very different from textbooks: e-mails are not always edited or revised carefully; they probably will be written to a single person, who will respond; and they may talk about the personal feelings and activities of the writer (see **E-mail, Internet, Chatroom Talk: Pragmatics**).

Different cultures recognize different registers. One way to figure out the registers in a culture is to list the text categories that have names, such as 'letters,' 'textbooks,' 'e-mail messages,' 'newspaper articles,' 'biographies,' 'shopping lists,' 'term papers,' 'novels,' and so on. However, registers can be defined at any level of generality, and more specialized registers may not have widely used names (see Biber, 1994). For example, 'academic prose' is a very general register, whereas 'methodology sections in experimental psychology articles' is a much more highly specified register.

Registers differ in their situational characteristics. They are planned to different extents, interactive to different extents, and addressed to different kinds of audiences. They also have different topics, and they are written with different goals or purposes.

Registers are identified by 'nonlinguistic' or 'situational' characteristics, such as the setting, the audience, interactiveness, and extent of planning. There have been numerous studies that describe the situational parameters that distinguish among registers (see, e.g., Crystal and Davy, 1969; Hymes, 1974; Brown and Fraser, 1979; Duranti, 1985; Biber, 1994). Several situational characteristics are identified in most of these frameworks, including the participants (including their relationships and their attitudes toward the communication); the setting (including factors such as the extent to which time and place are shared among participants and the level of formality); the channel (or mode) of communication; the production and processing circumstances; the purpose of communication; and the topic. A register can be defined by a particular combination of values for any (group) of these situational characteristics.

Although registers are defined in situational terms, they can also be described in terms of their typical linguistic characteristics. This is because linguistic features serve important communicative functions and therefore tend to occur in registers with certain situational characteristics. For example, first- and second-person pronouns (*I* and *you*) are especially common in conversation. These linguistic features are associated with the normal situational characteristics of conversation: speakers in conversation talk a great deal about themselves, and so they use the pronoun *I* a lot. They are also interactive, talking to another individual person, and so they also use the pronoun *you* a lot.

There are many studies that describe both the situational and linguistic characteristics of a particular register. These are often highly specialized registers, such as sports announcer talk (Ferguson, 1983), note-taking (Janda, 1985), personal ads (Bruthiaux, 1994), and classified advertising (Bruthiaux, 1996). Many register studies have also been carried out within a Hallidayan functional-systemic framework (see, e.g., Halliday, 1988, and the collection of papers in Ghadessy, 1988, which include descriptions of written sports commentary, press advertising, and business letters) (see **Halliday, Michael Alexander Kirkwood**). Several studies adopting this approach have been concerned with school-based registers and their implications for education generally (see, e.g., Martin, 1993). The academic journal *English for Specific Purposes* publishes articles that describe the characteristics of specialized registers, providing the foundation for more focused curricula for the teaching of English as a Foreign Language (see **Second and Foreign Language Learning and Teaching; Languages for Specific Purposes**).

In addition to the study of individual registers, many studies have made comparisons across registers, studying the patterns of 'register variation.' Register variation is inherent in human language: a single speaker will make systematic choices in pronunciation, morphology, word choice, and grammar, reflecting a range of situational factors. The ubiquitous nature of register variation has been noted by a number of scholars, such as Ure: "each language community has its own system of registers . . . corresponding to the range of activities in which its members normally engage" (1982: 5); Ferguson: "register variation, in which language structure varies in accordance with the occasions of use, is all-pervasive in human language" (1983: 154); or Hymes: "no human being talks the same way all the time At the very least, a variety of registers and styles is used and encountered" (1984: 44).

Comparative register analyses are important for two major arenas of linguistic research: (1) linguistic descriptions of lexical and grammatical features, and (2) descriptions of the registers themselves. With respect to traditional lexical and grammatical descriptions, register studies have shown that functional descriptions of a grammatical feature are generally not valid for the language as a whole. Rather, characteristics of the textual environment interact with register differences, so that strong patterns of use in one register often represent only weak patterns in other registers. For register descriptions, a comparative register perspective provides the baseline needed to understand the linguistic characteristics of any individual register.

Register differences can exist at any linguistic level. The following sections discuss some of these differences at the lexical, grammatical, and lexico-grammatical levels. Then, I return to the description of registers and the overall patterns of register variation.

Lexical and Grammatical Differences among Registers

One analytical approach that has been especially productive for studying register variation is corpus-based analysis, with its emphasis on the representativeness of the database, and its computational tools for investigating distributional patterns across registers and across discourse contexts in large text collections (see McEnery and Wilson, 1996; Biber *et al.*, 1998; Kennedy, 1998; Meyer, 2002; and Hunston, 2002 for introductions to this analytical approach). The *Longman grammar of spoken and written English* (LGSWE; Biber *et al.*, 1999) applies corpus-based analyses to show how any grammatical feature can be described for both its structural characteristics and its patterns of use across spoken and written registers. The analyses in the LGSWE are based on texts from four registers: conversation, fiction, newspaper language, and academic prose. Although these are general registers, they differ from one another in important ways (e.g., with respect to mode, interactiveness, production circumstances, purpose, and target audience). The analyses were carried out on the Longman Spoken and Written English (LSWE) Corpus, which contains ca. 40 million words of text overall, with ca. 4–5 million words from each of these four registers. Selected analyses from the LGSWE are used in the following sections to illustrate the systematic lexical and grammatical differences found across registers.

Lexical Differences across Registers

Probably the most obvious linguistic difference among registers is word choice. For example, in conversation we rely heavily on vague nouns with general content – such as *stuff* and *thing* – whereas these nouns are rarely used in registers such as textbooks or newspaper editorials.

In fact, the most common words in each word class show sharp differences among registers. **Table 1** shows some of the contrasts between the common verbs, adjectives, and adverbs used in conversation versus the words belonging to the same lexical categories used in academic prose.

Similar differences could easily be identified for other registers. In part, these differences reflect the different topics and communicative purposes

Table 1 Selected common verbs, adjectives, and adverbs in conversation versus academic prose

Conversation	Academic prose
Verbs	
<i>Get</i>	Produce
<i>Go</i>	Provide
<i>Come</i>	Obtain
<i>Make</i>	Form
<i>Take</i>	Describe
<i>Say</i>	Develop
<i>Know</i>	Require
<i>Think</i>	Occur
<i>See</i>	Involve
<i>Want</i>	Include
Adjectives	
<i>Big</i>	Same
<i>Little</i>	Different
<i>Old</i>	Important
<i>Good</i>	Necessary
<i>Nice</i>	Difficult
<i>Sure</i>	Possible
<i>Right</i>	Likely
Adverbs	
<i>Just</i>	Often
<i>Really</i>	Usually
<i>Too</i>	Especially
<i>Pretty</i>	Relatively
<i>Real</i>	Particularly
<i>Like</i>	Generally
<i>Maybe</i>	Indeed

Source: Based on LGSWE (Biber *et al.*, 1999: 512–513, 517, 561–562).

typically associated with a register. However, these differences can also reflect conventional associations of particular words with particular situations of use.

Grammatical Differences across Registers

Although they are not as easily noticed, grammatical differences among registers are as pervasive as lexical differences. The descriptions in the LGSWE show that nearly any grammatical feature will be distributed in systematic ways across registers. **Tables 2 and 3** contrast some of the most important distinctive grammatical characteristics of conversation versus academic prose.

Many of the grammatical features typical of conversation listed in **Table 2** reflect a heavy reliance on verbs, adverbs, and pronouns instead of complex noun phrases. These features result in the dense use of short, simple clauses. However, it also turns out that several dependent clause features are much more common in conversation than other registers. These are mostly complement clauses controlled by verbs, especially *that*-clauses (the complementizer *that* is

frequently omitted in these structures). These features are often used to express 'stance' in conversation: the controlling verb expresses the stance, and the complement clause contains the new information, for example, *I just think [it's cool]* or *I know [what you're talking about]*.

The typical characteristics of conversation can be contrasted with the typical features of academic prose. Three different word classes are especially prevalent in academic prose: nouns, adjectives, and prepositions. Overall, these grammatical classes are more frequent in academic prose than in other registers, but there are many related specific features that are especially characteristic of academic prose (e.g., nominalizations, noun phrases with multiple modifiers). In contrast, verbs overall are much less common in academic prose than in other registers, although there are specific verb categories that are especially common in academic prose (e.g., copula *be*, existence verbs, derived verbs, and passive voice verbs). Similarly, there are specific categories of adverbs and adverbials (e.g., linking adverbials) that are especially common in academic prose. **Table 3** lists some of the major grammatical features that are especially common in academic prose.

A comparison of the typical linguistic characteristics of conversation and academic prose reveals

several unanticipated differences, showing how empirical register analyses can run counter to our prior expectations. One of the most surprising differences relates to the use of dependent clauses, contradicting the widespread belief that academic prose is more 'complex' than conversation and that dependent clauses are therefore especially common in academic prose. Rather, empirical register studies have shown that only some dependent clause types are common in written registers and that specific clause types have their own distributions among registers. For example, finite relative clauses are much more common in writing than in conversation, but they are most common in newspaper writing and fiction rather than in academic prose. However, relative clauses with the relative pronoun *which* are most frequent in academic prose. Nonfinite relative clauses (*-ing* clauses and *-ed* clauses) are also most common in academic prose (although they are frequently found in newspaper writing as well) (see **Media: Pragmatics**).

Other dependent clause types turn out to be more common in speech. For example, many complement clause types are much more common in conversation than in academic prose (see **Table 2**). These complement clauses often serve important stance functions in conversation (e.g., *I think that...*; *I don't know what...*; *I want to...*), making them an especially

Table 2 Grammatical features that are especially common in conversation

Feature	Pattern of use
Verbs and verb phrases	
Verbs, overall	Verbs are much more common in conversation than in informational written registers (almost 1/3 of all content words in conversation are lexical verbs) (p. 65, 359)
Mental verbs	Mental verbs (e.g., <i>know</i> , <i>think</i> , <i>see</i> , <i>want</i> , <i>mean</i>) are more common in conversation (p. 366, 368)
Modal verbs	Modal verbs are also much more common in conversation than in the written registers, especially <i>can</i> , <i>will</i> , <i>would</i> (p. 486 ff.); semimodal verbs (such as <i>especially</i> , <i>have to</i> , (<i>had</i>) <i>better</i> , (<i>have</i>) <i>got to</i> , <i>used to</i>) are common only in conversation (p. 486 ff.)
Tense and aspect	ca. 70% of all verb phrases in conversation are present tense (p. 456 ff.); the progressive aspect (verb + <i>-ing</i>) is common in conversation (and fiction) (p. 462 ff.)
Adverbs	
Simple adverbs	Most common in conversation (pp. 540–542)
Adjectives used as adverbs	Common only in conversation, e.g., <i>It's running real good</i> (pp. 542–543)
Adverbs of 'stance'	Most common in conversation, especially <i>really</i> , <i>actually</i> , <i>like</i> , <i>maybe</i> (pp. 859, 867–871)
Pronouns	
Personal pronouns	Most common in conversation, especially <i>I</i> , <i>you</i> , <i>it</i> (pp. 92, 235, 237, 333–334)
Demonstrative pronoun <i>that</i>	Extremely common only in conversation (pp. 349–350)
Simple clauses	
Questions	Common only in conversation (p. 211 ff.)
Imperatives	Common only in conversation (pp. 221–222)
Coordination 'tags'	Common only in conversation, e.g., <i>or something</i> (but note the use of <i>etc.</i> in writing) (pp. 116–117)
Dependent clauses	
Verb + <i>that</i> -clause	Most common in conversation, especially <i>think</i> , <i>know</i> , <i>guess</i> , + <i>that</i> -clause (pp. 668–670, 674–675); overall, over 80% of all <i>that</i> -clauses in conversation omit <i>that</i> (pp. 680–683)

Source: Based on a survey of LGSWE (Biber *et al.*, 1999). Page numbers refer to specific pages in the LGSWE.

Table 3 Some grammatical features that are especially common in academic prose

Feature	Pattern of use
Nouns and noun phrases	
Nouns, overall	Approximately 60% of all content words in academic prose are nouns (p. 65)
Pronouns	Nouns are much more common than pronouns in academic prose, especially in object positions (pp. 235–236); as to specific pronouns, such as <i>this</i> and generic <i>one</i> , they are much more common in academic prose (pp. 349–350, 354–355); <i>this</i> is used for immediate textual reference, whereas <i>one</i> is used for generic rather than specific reference
Plural nouns	Much more common in writing than in conversation; most common in academic prose (pp. 291–292)
Nominalizations	Much more common in academic prose, especially nouns formed with <i>-tion</i> and <i>-ity</i> (pp. 322–323)
Definite article <i>the</i>	Much more common in writing than in conversation; most common in academic prose (pp. 267–269)
Demonstratives	Most common in academic prose; especially <i>this</i> and <i>these</i> (p. 270, 274–275)
Modifiers	60% of all noun phrases in academic prose have a modifier (p. 578)
Adjectives	
Adjectives, overall	Adjectives are much more common in academic prose than in conversation or fiction (pp. 65, 506)
Attributive adjectives	Much more common in academic prose (pp. 506, 589)
Derived adjectives	Much more common in academic prose, especially adjectives formed with <i>-al</i> (pp. 531–533)
Verbs and verb phrases	
Copular verbs <i>be</i> , <i>become</i>	Most common in academic prose (pp. 359–360, 437–439)
Existence verbs	Much more common in writing than in conversation; most common in academic prose (e.g., <i>include</i> , <i>involve</i> , <i>indicate</i>) (pp. 366, 369, 419)
Verbs with inanimate subjects	Common only in academic prose (e.g., <i>this quotation shows</i> ; <i>the test sequence proves</i>) (pp. 378–380)
Derived verbs	Most common in academic prose, especially verbs formed with <i>re-</i> and <i>-ize</i> (pp. 400–403)
Passive voice	Much more common in academic prose, especially the ‘short’ passive (without <i>by</i> -phrase) (pp. 476–480, 937–940)
Adverbs and adverbials	
Linking adverbials	Most common in academic prose, especially <i>however</i> , <i>thus</i> , <i>therefore</i> , <i>for example</i> (e.g.) (pp. 766, 880–882)
Purpose and concessive adverbials	Most common in academic prose (<i>in order to</i> , <i>so as to</i> , <i>even</i> , (<i>al</i>) <i>though</i> , <i>albeit</i> , etc.) (pp. 784, 786, 820–821, 824–826)
Dependent clause features	
Relative clauses with the relative pronoun <i>which</i>	Most common in academic prose (pp. 609–612)
Noun + <i>that</i> -complement clause	Most common in academic prose (e.g., <i>the fact that ...</i>); frequent head nouns are <i>fact</i> , <i>possibility</i> , <i>doubt</i> , <i>belief</i> , <i>assumption</i> (pp. 647–651)
Abstract noun + <i>of</i> + <i>ing</i> -clause	Most common in academic prose (e.g., <i>methods of assessing error</i>); frequent head nouns are <i>way</i> , <i>cost</i> , <i>means</i> , <i>method</i> , <i>possibility</i> , <i>effect</i> , <i>problem</i> , <i>process</i> , <i>risk</i> (pp. 653–655)
Extraposed clauses	Most common in academic prose, especially <i>that</i> -clauses controlled by the adjectives <i>clear</i> , (<i>un</i>) <i>likely</i> , and (<i>im</i>) <i>possible</i> (e.g., <i>it is likely that ...</i>), and <i>to</i> -clauses controlled by adjectives (e.g., <i>it is important to ...</i>) (pp. 672–675)
<i>ing</i> -clauses controlled by adjectives	Most common in academic prose (e.g., <i>capable of</i> , <i>important for/in</i> , <i>useful for/in</i>) (p. 749)
Concessive adverbial clauses	Most common in academic prose (and newspapers) (pp. 820–825)
Other features	
Prepositions	Most common in academic prose (p. 92)
<i>Of</i> -phrases	Much more common in writing than in conversation; most common in academic prose (pp. 301–302)
Stance noun + <i>of</i> -phrase	Most common in academic prose, especially <i>possibility of</i> , <i>value of</i> , <i>importance of</i> , <i>problem of</i> , <i>understanding of</i> (pp. 984–986)
Dual-gender reference	Common only in academic prose (<i>he or she</i> , <i>his or her</i> , <i>he/she</i>) (pp. 316–317)

Source: Based on a survey of the LGSWE (Biber *et al.*, 1999). Page numbers refer to specific pages in the LGSWE.

frequent and important part of everyday interactions. Only one major type of complement clause is especially characteristic of academic prose: extraposed clauses controlled by adjectives (e.g., *It is possible that ...*, *It is important to ...*). Adverbial clauses have a different distribution across registers, being most

common overall in fiction. However, conversation also uses adverbial clauses to a slightly greater extent than academic prose (and conditional clauses are especially common in conversation). Only one subtype of adverbial clause is especially frequent in academic prose: concessive clauses.

Overall Patterns of Register Variation: The MD Approach

As noted above, a complementary research goal is to describe the general characteristics of a register and the overall patterns of register variation in a language. Despite the fundamental importance of register variation, there have been few comprehensive analyses of the register differences in a language. This gap is due mostly to methodological difficulties: until recently, it has not been feasible to analyze the full range of texts, registers, and linguistic characteristics required for comprehensive analyses of register variation. With the availability of large on-line text corpora and computational analytical tools, such analyses have become possible. (see **Computational Linguistics: Overview**).

The multidimensional (MD) analytical approach was developed for the comprehensive analysis of register variation, to discover and interpret the patterns of linguistic variation among registers in a corpus of texts (see, e.g., Biber, 1988). Early researchers in sociolinguistics (e.g., Ervin-Tripp, 1972; Hymes, 1974) argued that linguistic features work together in texts as constellations of co-occurring features (rather than as individual features) to distinguish among registers. Although this theoretical perspective is widely accepted, linguists lacked the methodological tools required to identify these co-occurrence patterns before the availability of corpus-based analytical techniques. MD analysis provides these tools, using automatic corpus analysis to analyze the quantitative distribution of numerous linguistic features across the texts and text varieties of a corpus and multivariate statistical techniques (especially factor analysis) to identify the co-occurrence patterns among features.

The dimensions identified in MD analysis have a linguistic basis, but they are interpreted functionally. The linguistic dimension exhibits a group of features (e.g., nouns, attributive adjectives, prepositional phrases) that co-occur with a markedly high frequency in texts. These co-occurrence patterns are interpreted to assess their underlying situational, social, and cognitive functions. For example, the frequent co-occurrence of first-person pronouns, second-person pronouns, hedges, and emphatics in conversational texts is interpreted as reflecting directly interactive situations and a primary focus on personal stance and involvement (see **Mitigation**).

Biber (1988) identified five main dimensions of variation in a general corpus of spoken and written registers. He used factor analysis to identify the groups of linguistic features associated with each dimension (i.e., the linguistic features that co-occur in texts with

markedly high frequencies). The co-occurring groupings of features on each dimension reflect distinct functional relations, indicated by the interpretive labels for each one: *Involved versus informational production*, *Narrative discourse*, *Situation-dependent versus elaborated reference*, *Overt expression of persuasion*, and *Impersonal style*. Biber (1988: Chap. 6–7; 1995: Chap. 5–7) and Conrad and Biber (2001: Chap. 2) provided detailed justification for these interpretations based on the shared communicative functions of the co-occurring linguistic features on each dimension plus the distribution of registers along each dimension.

MD analyses of register variation in English have been carried out by numerous researchers focusing on a wide range of specific research questions. The papers by Atkinson, Burges, Connor-Linton, Conrad, Helt, Shohamy, Reppen, and Rey (all included in Conrad and Biber, 2001) provide a sampling of MD studies by U.S.-based scholars.

Early MD studies investigated the synchronic relations among spoken and written registers in English (e.g., Biber, 1988), whereas later studies focused on diachronic register variation (e.g., Biber, 1995; Biber and Finegan, 1989a), more specialized discourse domains (e.g., Biber *et al.*, 2002; Conrad, 1996, 2001; Connor and Upton, 2003), and the patterns of register variation in other languages (e.g., Kim and Biber, 1994 on Korean; Biber and Hared, 1992 on Somali). Biber (1995) synthesized these studies to investigate the extent to which the underlying dimensions of variation and the relations among registers are configured in similar ways across languages.

Conclusion

This article has surveyed the kinds of situational and linguistic differences that distinguish among registers. Registers differ with respect to a wide array of situational characteristics, relating to purpose, topic, physical setting, production circumstances, and the relations among participants. These situational differences are associated with important linguistic differences at the lexical, grammatical, and lexico-grammatical levels. Furthermore, corpus-based analytical techniques can be employed to identify the linguistic co-occurrence patterns that regularly occur in texts from different registers, providing the basis for comprehensive analyses of register variation.

All language users adapt their language to different situations of use. It would be nearly impossible to spend an entire day using only one register – only having casual conversations, or only reading a news-

paper, or only writing an academic paper. Rather, switching among registers is as natural as human language itself. Consequently, the study of register variation is not a supplement to the description of grammar, discourse, and language use; rather, it is central to these enterprises.

Relevance Theory

F Yus, University of Alicante, Alicante, Spain

© 2006 Elsevier Ltd. All rights reserved.

Relevance theory (henceforth RT), a cognitive theory of human communication developed by D. Sperber and D. Wilson, was fully described in their 1986 book (Sperber and Wilson, 1986, 2nd edn., 1995), but it really emerged in the late 1970s and early 1980s as a cognition-centered alternative to Grice's cooperation-ruled explanation of human communication (see Wilson and Sperber, 1981). Since then, it has been a highly influential theory in pragmatics producing a good number of studies backing it up, criticizing it, or applying it to different pragmatic research areas (see Yus, 1998; Wilson and Sperber, 2002a; and RT Bibliography).

The main assumption of the theory is that human beings are endowed with a biologically rooted ability to maximize the relevance of incoming stimuli (including linguistic utterances and other communicative behavior). Relevance is not only a typical property of external stimuli (e.g., utterances), but also of internal representations and thoughts, all of which may become inputs for cognitive processing. The pursuit of relevance is a typical aspect of the mental activity of human beings, always geared to obtaining the highest reward from the stimuli that they process. This biological endowment is the result of the evolution of the architecture and complexity of the human mind and part of a general human ability to meta-represent one's and other people's thoughts and intentions: "As a result of constant selection pressure towards increasing efficiency, the human cognitive system has developed in such a way that our perceptual mechanisms tend automatically to pick out potentially relevant stimuli, our memory retrieval mechanisms tend automatically to activate potentially relevant assumptions, and our inferential mechanisms tend spontaneously to process them in the most productive way" (Wilson and Sperber, 2002a: 254). Together with another uniquely human cognitive endowment, the ability to metarepresent one's and other people's thoughts and intentions, this tendency to maximize relevance allows us to predict what information is likely to be relevant to other people and what interpretive steps might be involved in its processing, and therefore allows for the manipulation of other people's thoughts.

Basic Claims

Four statements can summarize this theory (Wilson, 1994: 44): (a) the decoded meaning of the sentence

is compatible with a number of different interpretations in the same context; (b) these interpretations are graded in terms of accessibility; (c) hearers rely on a powerful criterion when selecting the most appropriate interpretation; and (d) this criterion makes it possible to select one interpretation among the range of possible interpretations, to the extent that when a first interpretation is considered a candidate matching the intended interpretation, the hearer will stop at this point.

These statements can be broken down into a number of basic claims, as summarized below.

Code versus Inference

Unlike the so-called **code model** of communication, according to which messages are simply coded and decoded, Sperber and Wilson favor an **inferential model** in which decoding plays a minor role compared with the inferential activity of the interpreter. Within this approach, the decoding of utterances underdetermines their interpretation and serves rather as a piece of evidence about the speaker's meaning. Verbal communication does involve the use of a code (i.e., the grammar of the language), but inference plays a major role in turning the schematic coded input into fully propositional interpretations.

One of the most interesting contributions of RT is, precisely, the claim that there is a wide gap between the (coded) sentence meaning and the (inferred) speaker's meaning, which has to be filled inferentially. Comprehension starts at the context-free identification of the utterance's logical form, which is then enriched to yield explicit information (**explicatures**) and/or implicit information (**implicatures**) (see **Implicature**).

A Post-Gricean Theory

Sperber and Wilson acknowledge the filiation of RT from Grice's view of communication, but there are several aspects in which they depart from Grice. This is the reason why we can call RT a post-Gricean theory (see **Neo-Gricean Pragmatics**), a theory that takes the Gricean approach to communication as a mere starting point, as opposed to neo-Gricean theories which stay much closer to Grice's cooperative principle and its maxims (see **Grice**, **Herbert Paul**; **Cooperative Principle**; **Maxims and Flouting**). Several points deserve explanation:

1. One of the major contributions by Grice was to underline the role that intentions (roughly defined as mental representations of a desired state of affairs) play in human communication. His emphasis on the expression and recognition of

intentions laid the foundations of the inferential model of communication. Crucially to Grice, the hearer explains the speaker's communicative behavior by identifying the underlying intention, a typically human form of mind-reading activity. However, Sperber and Wilson do not agree with the complex schema of human reasoning that Grice proposed for the derivation of implicatures.

Sperber and Wilson also point out that Grice's emphasis on the role of intentions corroborates the fact that communication can exist without the need for a code. All that the communicator has to do to communicate a thought is to get the addressee to recognize his/her intention to convey it.

Sperber and Wilson distinguish two levels of intention: **informative** (an intention to inform the hearer of something) and **communicative** (the intention to inform the addressee of that informative intention). In inferential communication, the identification of the informative intention is done through the identification of the communicative intention, the process being activated by verbal ostensive communication, in which it is clear to both speaker and hearer (**mutually manifest** in Sperber and Wilson's terminology) that the speaker has the (metarepresentational) intention to communicate something. Unlike other forms of information transmission, 'ostensive inferential communication' involves both types of intention, and is achieved by ostensively providing an addressee with evidence that helps him/her infer the speaker's meaning.

2. RT explains the hearer's inference of the (intended) speaker's meaning from the coded sentence meaning by resorting to another central claim suggested by Grice: that ostensively communicated utterances automatically generate expectations that activate the hearer's search for the speaker's meaning. But whereas Grice explained these expectations in terms of the assumption by hearers that speakers were observing the cooperative principle and its maxims, within RT these expectations are explained in cognitive terms (basically proposing the existence of a Cognitive Principle of Relevance), without reliance on a cooperative principle.
3. For Sperber and Wilson, no maxims, in the Gricean sense, are required for the explanation of communication. This is especially evident in the case of the Maxim of Quality (roughly, 'tell the truth'), which Grice proposed for the explanation of figurative language and irony. Sperber and Wilson have shown that people are normally 'loose' when they speak and only on very specific occasions do they intend their utterances to be regarded as literally true. In addition, Sperber and Wilson propose that

all uses of language, whether loose (metaphor, hyperbole, etc.) literal can be addressed with a single explanatory framework based on general expectations of relevance.

Two Principles of Relevance

Initially, Sperber and Wilson proposed one Principle of Relevance to account for the fact that an act of 'ostension' carries a guarantee of its eventual relevance, but in the Postface to the second edition of their book (Sperber and Wilson, 1995: 260ff.), they propose that we can distinguish a broad **cognitive principle of relevance**: "human cognition tends to be geared to the maximisation of relevance," as well as a narrower (**communicative principle of relevance**: "every act of ostensive communication communicates a presumption of its own optimal relevance"; 1986: 158), the latter being the main focus of analysis within pragmatics. But the former is important, too, because it stresses the fact that we are biologically geared toward processing the most relevant inputs available. In addition, it is this evolved disposition that allows for the prediction of the mental states of others, which is crucial in human communication.

The communicative principle involves a definition of optimal relevance comprising two parts: (a) The ostensive stimulus is relevant enough for it to be worth the addressee's effort to process it; and (b) The ostensive stimulus is the most relevant one compatible with the communicator's abilities and preferences (Sperber and Wilson, 1995: 267, 270). As Wilson and Sperber (2002a: 257–258) correctly point out, communicators "cannot be expected to go against their own interests and preferences in producing an utterance. There may be relevant information that they are unable or unwilling to provide, and ostensive stimuli that would convey their intentions more economically, but that they are unwilling to produce, or unable to think of at the time." All this is covered by clause (b) of the definition of optimal relevance, which states that the ostensive stimulus is the most relevant one "that the communicator is WILLING AND ABLE to produce" (Sperber and Wilson, 1995: 258).

Assessing Relevance: Cognitive Effects versus Processing Effort

Unlike what is the case in 'static' pragmatics, which foregrounds the importance of context but somehow takes it for granted or is merely interested in dissecting, as it were, its elements, Sperber and Wilson's theory views the context as a dynamic, mental entity made up of a subset of the person's assumptions about the world; it is this subset that is accessed in

the search for relevance. Often several extensions of context are required to arrive at an optimally relevant interpretation, but as soon as one interpretation is found to be satisfactory, interpretation stops and no other interpretive hypotheses are considered: “When a hearer following the path of least effort finds an interpretation which satisfies his expectations of relevance, in the absence of contrary evidence, this is the best possible interpretive hypothesis” (Wilson and Sperber, 2002b: 605).

The aforementioned Communicative Principle of Relevance predicts a basic procedure for hearers when hypothesizing about contextual extensions required for the interpretation of a verbal stimulus: to consider interpretive hypotheses in order of accessibility (following a path of least effort) and to stop when they arrive at an interpretation which satisfies the expectations of relevance raised by the stimulus itself. Relevance, then, is a matter of balance between the interest that the utterance might provide (in terms of so-called ‘positive cognitive effects’) and the mental effort that obtaining this interest demands.

Relevance is a characteristic of an input to the human cognitive processes which, when processed in a certain context, yields positive cognitive effects. Because there are too many possible stimuli to which we can pay attention, our cognitive architecture is designed to allocate our processing effort in such a way that benefit is maximized. Hence, relevance has to do with the improvement of the person’s knowledge; this can be achieved either by adding new information, by revising existing assumptions, or by yielding new conclusions resulting from the combination of old and new information (in this case **contextual implicatures** are generated) (see **Context, Communicative**).

The definition of relevance of an input to an individual involves two clauses: “(a) everything else being equal, the greater the positive cognitive effects achieved in an individual by processing an input at a given time, the greater the relevance of the input to that individual at that time; and (b) everything else being equal, the smaller the processing effort expended by the individual in achieving those effects, the greater the relevance of the input to that individual at that time” (Wilson and Sperber, 2002b: 602).

Current Issues and Open Debates

The Explicit/Implicit Distinction

One of the key differences between Grice’s model and Sperber and Wilson’s lies in the demarcation of explicit and implicit communication. For Grice, **what is said** involved little inference, mainly reduced to

disambiguation and reference assignment, while all the inferential load was laid upon the derivation of implicatures, the latter being obtained **after** an interpretation reduced to the literal meaning has been found inappropriate, in a so-called **dual-stage processing**. Sperber and Wilson reject this view and favor a more adequate, **mutual parallel adjustment** of explicit content – explicatures – and implicit import – implicatures – during interpretation, and with no preconceived sequential arrangement.

Within RT, explicitly communicated information not only demands as much contextualization as do implicatures, but also covers aspects of communicated meaning which Grice included in the term implicature (e.g., the so-called **generalized conversational implicatures**, most of which are now pictured as explicit information, see Levinson, 2000; Carston, 2002).

In addition to implicatures, Sperber and Wilson propose two types of explicitly communicated information: the **basic-level explicature**, and the **higher-level explicature**. The latter also includes the speaker’s attitude (*to regret that ... to be happy that ... etc.*) or a higher-order speech-act schema (*to be asking that ... to be ordering that ... etc.*). Both explicatures and implicatures allow for degrees (i.e., strong and weak explicatures/implicatures), depending on the addressee’s responsibility for their derivation and the amount of mental processing required.

Other notions used by other authors in the definition of explicit information, for instance **literal meaning** or **what is said**, are put into question by Sperber and Wilson, because these do not play any useful role in the study of verbal comprehension: “even when a literal meaning is available, it is not automatically the preferred interpretation of an utterance. In fact, literalness plays no role in our account of language comprehension, and nor does the notion of what is said” (Wilson and Sperber, 2002b: 586). This is because, among other reasons, hearers commonly derive loose interpretations rather than purely literal ones: “hearers have no objection to strictly false approximations as long as the conclusions they bother to derive from them are true. In fact, they might prefer the shorter approximations to their longer-winded but strictly true counterparts for reasons of economy of effort” (Wilson and Sperber, 2002b: 598).

Whereas Bach (1994) has proposed a third term, **implicature**, half-way between explicatures and implicatures, other authors, such as Vicente (2002), reject this blurring of the explicit/implicit dichotomy. The term ‘implicature’ covers several cases which would fit into Sperber and Wilson’s notion of explicature, basically being completions of the semantic representation of the sentence (e.g., ‘The table is too wide’ [to go through the door]) and nonliteral uses of

sentences in which no constituent is being used non-literally, what Bach calls **standardized nonliterality** (e.g., (said to a person who has cut himself) 'You are not going to die' [from this cut]).

Conceptual and Procedural Encoding

One of the most interesting lines of research within relevance theory is the one that differentiates between **conceptual meaning** and **procedural meaning**. Wilson and Sperber (1993: 10) summarize this dichotomy as follows: "inferential comprehension involves the construction and manipulation of conceptual representations; linguistic decoding feeds inferential comprehension; linguistic constructions might therefore be expected to encode two basic types of information: concepts or conceptual representations on the one hand, and procedures for manipulating them on the other."

Most words encode concepts, but some words give instructions as to how conceptual representations are to be manipulated and hence encode procedural meaning. Blakemore and her followers applied the notion to connectives (Blakemore, 1987) and discourse markers (Blakemore, 2002), which constrain the inferential phase by indicating the kind of inferential process that the hearer should go through (hence reducing the eventual overall effort) in the subsequent stretch of discourse. In recent research, the list of procedural items has been extended to cover nonverbal elements such as intonation.

Ad hoc Concept Formation

The notion of *ad hoc* concept construction is one of the latest developments of relevance theory in the area of figurative language (especially metaphors), which has also been extended to the analysis of how concepts in general are processed (cf. Carston, 2002; Pilkington, 2000).

The traditional relevance-theoretic account of figurative language relies on the assumption that there is an interpretive resemblance between the coded concept and the intended thought. And we can say the same about the whole utterance whose propositional form resembles the propositional form of the communicator's thought (Pilkington, 2000: 90). From this viewpoint, the interpretive resemblance between, for instance, a coded metaphor and the thought which it resembles would lead to the hearer's derivation of stronger/weaker implicatures.

Within an alternative account of utterance interpretation, it is claimed that the metaphor provides a new *ad hoc* concept for the proposition expressed by the utterance (instead of favoring the derivation of

implicatures) (see **Metaphor: Psychological Aspects**). Encyclopedic entries would be explored in such a way that an increase in the *salience* of a number of assumptions is created, providing an encyclopedic entry for the new concept (Pilkington, 2000: 95-96; for 'salience,' see Giora, 2002). They are *ad hoc* "because they are not linguistically given, but are constructed online in response to specific expectations of relevance raised in specific contexts. There is a difference then between *ad hoc* concepts, accessed by a spontaneous process of pragmatic inference, and lexicalized concepts, which are context-invariant" (Carston, 2002: 322).

Mutual Knowledge versus Mutual Manifestness

Sperber and Wilson reject the traditional notion of mutual knowledge because it generates an endless recursion (A knows that p, B knows that A knows that p, A knows that B knows that A knows that p, and so on). Instead, they propose the notion of **mutual manifestness** (see Sperber and Wilson, 1990). What is 'manifest' is what one is capable of inferring or capable of perceiving, even if one hasn't done so yet. The sum of all the manifest assumptions is the person's **cognitive environment**. A set of assumptions manifest to several individuals constitutes their shared cognitive environment. When it is manifest to all the people sharing a cognitive environment that they share it, then, this is a **mutual cognitive environment**, made up of mutually manifest assumptions. Communication is a matter of making certain assumptions mutually manifest to both speaker and hearer.

Several authors have criticized the notion of mutual manifestness. For example, Mey and Talbot (1988) point out that what Sperber and Wilson do is to send mutual knowledge out at the front door and then let it in at the back, disguised as 'mutually manifest assumptions.' For these authors, cognitive environments are not distinguishable from mutual knowledge; thus, Sperber and Wilson appear to be using the same concept that they want to abandon. To my knowledge, neither Sperber and Wilson nor their critics have been persuaded to abandon their differing claims on mutuality.

Communicated and Noncommunicated Acts

One of the most underdeveloped areas within relevance-theoretic research is the relationship between RT and speech acts. In short, Sperber and Wilson (1986: 244-246) distinguish between communicated and noncommunicated acts. The former depend on the addressee's perception that a certain

speech act has been performed (e.g., admitting, promising, thanking), while in non-communicated acts, communication does not depend on the identification of a particular speech act (e.g., predicting, warning, suggesting). In this case, successful communication lies in the hearer's recovery of adequate cognitive effects from the utterance with the aid of context and in the recovery of the speaker's intentions.

In his (2002) paper, Nicolle has argued against the existence of noncommunicated speech acts in the RT sense. Examples of noncommunicated acts (such as the act of warning in "The path is slippery here") are reconsidered by Nicolle in social terms, and their influence on the interlocutors' social environments implies that they also have to be communicated: "the recovery of information relating to social relations is an essential element of the comprehension process. When the recovery of such information depends on the identification of a particular speech act, that speech act is by definition a communicated act" (Nicolle, 2000: 239).

Irony and the Notion of Echo

In Wilson and Sperber (1992), the authors conceptualize irony in *interpretive* terms. An ironic utterance is an interpretation of another thought, utterance, or assumption that it resembles and which the speaker attributes to a different speaker or to himself/herself at another time. Ironic utterances are echoic, that is, they simultaneously refer to an attributed thought – or utterance, or assumption – and express an attitude to it. More specifically, the speaker's attitude toward what is echoed has to be dissociative. This dissociation may apply to either the proposition expressed by the utterance, or to some effect that is generated by that utterance.

Several authors have commented upon this proposal. For instance, in some of the papers collected in Carston and Uchida (1998) it is claimed that irony can be nonechoic. In their reply, Sperber and Wilson (1998) maintain that although most utterances cannot be understood as echoic (i.e., there is no accessible representation that they might be taken to echo), an utterance has to be echoic to be interpreted as ironical (*see Irony*).

Modularity

Initially, Sperber and Wilson adopted the view of the mental architecture of the mind proposed by Jerry Fodor in the early 1980s: several modules feeding a central processor with specific information.

Modules are evolved, special-purpose mental mechanisms, typically automatic, informationally encapsulated, and domain-specific. For instance, the

language module is only (and automatically) activated by verbal stimuli, feeding the central processor with a schematic logical form which then has to be enriched inferentially.

Over the last few years, this view of the mind has changed within RT (and also within evolutionary psychology), especially concerning the structure of the central processor, which is also regarded to be modular (Carston, 1997; Sperber and Wilson, 2002; Wilson, 2003). The most important module, specifically a submodule of the general 'theory of mind' ability, is **the pragmatic module**, which also exhibits qualities typically associated with modules. For example, this pragmatic module is biologically endowed, only activated by a specific type of information (ostensively communicated information), and constrained by its own principle: the Communicative Principle of Relevance.

Relevance Theory as Asocial

RT has been criticized for being hyperindividualistic and for avoiding the social aspects of communication (Mey and Talbot, 1988). Sperber and Wilson (1997: 147) acknowledge that they have concentrated on the inferential activity of the individual, but inferential communication is **also** essentially social: "Inferential communication is intrinsically social, not just because it is a form of interaction, but also, less trivially, because it exploits and enlarges the scope of basic forms of social cognition. Right or wrong, this is a strong sociological claim." Although Sperber and Wilson have not studied uses of communication to convey information about the social relationship between the interlocutors, they do not mean to deny its importance, or to express a lack of interest in the issues or the work done; they merely feel that, at this stage, they can best contribute to the study of human communication by taking it at its most elementary level, and abstracting away from these more complex (socially connoted) aspects (Sperber and Wilson, 1997). Hence, for them, although "so far, the contribution of relevance theory to the study of human communication has been at a fairly abstract level... it seems to us to have potential implications at a more concrete sociolinguistic level" (Sperber and Wilson, 1997: 148).

A proposal by Escandell-Vidal (2004) aims at integrating inferential and social issues in terms of principles and norms, respectively, and as part of a domain-specific picture of mental activity. The mind operates according to principles that are in charge of obtaining fully propositional interpretations from coded stimuli. When dealing with norms, the mind is engaged in both a long-term and a short-term task.

The short-term one analyzes and categorizes incoming information, and the long-term task builds up and updates socially accepted behavior.

Empirical Evidence

A common criticism of RT is that it is highly speculative, predicting without empirical evidence the mental procedures and interpretive steps the human mind goes through in human communication. Obviously, we are dealing with an object of study, the human mind, which is highly complex and still largely unexplained.

Sperber and Wilson (2002: 143) acknowledge that in much pragmatic research, there is a certain reluctance to get down to experimentation. However, relevance theorists have been particularly eager to combine theoretical issues with all the possibilities of testing provided by the careful use of linguistic intuitions, observational data, and the experimental methods of cognitive psychology (see Wilson and Sperber, 2002b: 607, note 7 for references). Recent research has aimed at an empirical explanation of central claims of the theory. For instance, Van der Henst and Sperber (2004) review various experimental tests of the two Principles of Relevance. They claim that the hypothesis that hearers spontaneously rely on a relevance-guided interpretive procedure can be experimentally tested either by intentionally manipulating the effort required to process a stimulus or by changing the order of accessibility of several competing interpretations for the same stimulus. Another possible test is a manipulation of the effect factor by making a specific interpretation more or less likely to satisfy the expectations of relevance.

Other studies have focused on other possible areas of RT-based empirical research. Among them we can underline the ones on the Wason selection task. For example, Sperber *et al.* (1995) tested how participants derive implications from conditional statements in order of accessibility, stop when their search for relevance reaches an adequate balance of cognitive effects and processing effort, and select cards on the basis of this interpretation. The authors were able to manipulate the effort and effect factors by varying the content and context of the conditional statement, so as to elicit correct or incorrect selections at will (cf. Wilson and Sperber, 2002a: 279).

The plausibility of a Gricean maxim of truthfulness to explain human communication has also been tested (Van der Henst *et al.*, 2002). These authors showed that when people ask a stranger the time in the street they get, as a reply, “a time that is either accurate to the minute or rounded to the nearest multiple of five,

depending on how useful in the circumstances they think a more accurate answer would be” (Wilson and Sperber, 2002b: 598), regardless of whether the people asked have (accurate) digital watches. These rounded answers are not strictly true, but they are easier for their audience to process.

Applications

RT has been applied to a number of research areas, among which we can distinguish the following.

1. **Grammar.** For RT the interest lies in how grammatical attributes constrain the choice of a candidate interpretation. In this sense, the grammatical arrangement of utterances plays an important part throughout this cognitive contextualization. From this point of view, several aspects of grammar have been addressed, including connectives (often within a conceptual/procedural account), conditionals, modals and modality, adverbs and adverbials, mood(s), tense(s), the article, etc.
2. **Humor.** Within a relevance-theoretic approach, humor is no longer a property of texts and, instead, what we need to characterize are the audience's mental processes in the interpretation of humorous texts.

Underlying this approach to humor lies the premise that communicators can predict and manipulate the mental states of others. Knowing that the addressee is likely to pick out the most relevant interpretation of the joke (or some part of it), the humorist may be able to produce a text that is likely to lead to the selection of an accessible interpretation, which is then invalidated at some point. In Yus (2003), for instance, it is claimed that in many jokes the initial part has multiple interpretations, which are graded according to their accessibility. The hearer is led to select an overt (i.e., relevant) interpretation of this part of the joke. Suddenly, the hearer notices that the subsequent part has a single covert interpretation which is eventually found to be the correct one (and the one providing a coherent interpretation to the whole text) and which humorously surprises the hearer (see **Humor in Language; Accessibility Theory**).

3. **Media discourses.** RT has also been successfully applied to the interpretation of media discourses, including films, newspaper headlines, comics, Internet discourse, and advertising. The last one is probably one of the most extensive applications of the theory. The control over the amount of information provided, the predictability of consumers'

responses, and the calculation of the effort required to process information, all typical features of the strategies by the advertisement makers, can easily be analyzed using a relevance–theoretical approach (see Tanaka, 1994).

4. **Literature.** Several studies have applied RT to literary discourse (Pilkington, 2000 is an example). Within an RT approach, literariness has to be analyzed as cognitive effects triggered by textual stimuli, involving special mental processes which, through a relevance-driven cognitive exploration, result in the marginally increased salience of a wide range of assumptions (Pilkington, 2000: 189). Because in literature it is more difficult (if not impossible) to make assumptions mutually manifest, a greater load of responsibility is laid upon the reader in extracting the intended (or, alternatively, his/her own) interpretation of the text, plus whatever feelings and emotions are associated with the comprehension of the text.
5. **Politeness.** This is a typical social feature of communication that somehow appears not to suit the individual-centered approach within RT (see **Politeness**). However, several studies have attempted an explanation of politeness in relevance–theoretic terms. For instance, politeness has been explained within RT as a verbal strategy compatible or incompatible with the background expectations about the current relationship holding between speaker and hearer, thus leading to different relevance-oriented interpretive paths (see Jary, 1998).
6. **Translation.** In RT-bases studies such as Gutt's (2000), there is a tendency to exploit the idea of resemblance between the intended interpretations of utterances. (For an account of relevance–theoretic applications to translation, see **Translation, Pragmatics**.)

Concluding Remarks

In RT, Sperber and Wilson propose a coherent cognitive account of how the human mind proceeds when attempting to select a plausible interpretation of ostensively communicated stimuli. They rely on the hypothesis that a biologically rooted search for relevance aids human beings in the inferential enrichment of typically underdetermined coded texts and utterances resulting in fully propositional interpretations.

The theory has provided insights in several debates in pragmatics and cognitive science and has been applied to a good number of research areas. Undoubtedly, RT will continue to stir fruitful intellectual debates on the explanation of human communication.

Reported Speech: Pragmatic Aspects

W Bublitz and M Bednarek, Universität Augsburg,
Augsburg, Germany

© 2006 Elsevier Ltd. All rights reserved.

Every speech event involves a speaker, who usually commits him- or herself to its propositional, functional, and evaluative contents. But we can also refer to utterances of others and report what they said, wrote, meant, or thought. Reporting, a metalinguistic act, may be done through quoting (direct speech, *oratio recta*), paraphrasing (indirect speech, *oratio obliqua*) or in other ways and can relate to every aspect of an utterance. It is a powerful communicative strategy, whose different pragmatic functions are conventionalized (e.g., as a way of characterizing speakers rather than reproducing their utterances) or merely rhetorical (Roncador, 1988).

Multifunctionality of Reported Speech

Reported speech is multifunctional on several levels. On a very general level of establishing social order through talk, speakers report in order to display their understanding both of what occurred during a previous conversation and how it fits into the current communicative event. On a more pragmatic level, and with different degrees of authenticity and correspondence with the reported speech event, the reporter may simultaneously relate the propositional and functional content of the reported discourse, its

contextual and situational environment, the way in which it was presented, and the speaker's (and/or the reporter's) emotional state and attitudinal stance.

Evaluative Functions

Evaluation is the central pragmatic function of reported speech. It can be related to its three main components: the source (who is responsible for the reported proposition), the reporting expression (referring to the source's saying), and the reported proposition(s) (what is reported).

The Source

Descriptions and qualifications of the source can be used strategically by speakers with the aim of influencing the hearer's judgment of the reliability of what is reported.

Credentializing Giving high credibility to one's source (credentializing) is a means of giving high credibility to the reported proposition(s) (Stubbs, 1986; Fairclough, 1988; Hunston, 2000). In general, speakers pursuing this technique assume that the more reliable and credible (in other words, the more expert) the source is portrayed as, the more reliability will be attached to the content of the reported speech by the hearer. This technique also includes references to well-known, universally accepted authorities, as in *As Chomsky reminds us, "revolutionary new ideas appear infrequently"* (Haiman, 1989: 137). The qualification of the source may include further

evaluation by means of attributive adjectives, as in *The noted educationalist A. H. Halsey has claimed that p* (Stubbs, 1986: 3).

Power and Solidarity Descriptions of sources can also be varied according to degrees of intimacy and distance. In studies on naming practices, the difference between referring to partners by first name (FN) and by title and last name (TLN) is related to the notions of intimacy and power (see **Power and Pragmatics**). Assuming that this practice can be transferred to ways of referring, reference to FN seeks to establish intimacy with and/or powerlessness of the referent, whereas reference to TLN establishes the referent as distant and/or powerful. Such references again involve the speaker's evaluation of the source, an evaluation that may be transferred to the evaluation of the reported proposition.

Labeling If sources are not explicitly identified by their names, labels are often employed to refer to them; such labels may be potentially evaluative. In newspapers, references to unspecified sources, experts, officials, professionals, etc., are extremely frequent. Labels like these are highly indeterminate in their referential meaning but imply more reliability than do other semantically vague labels (*a woman, a man*). The labels suggest that there was some well-founded reason for the journalist's consulting the reported speaker, namely that she or he is an authority on the matter. They imply the reliability of sources without having to identify them. Metonymy can be used to a similar effect, implying authority and/or reliability without mentioning named speakers (e.g., metonymic references to countries, institutions, etc.) (see **Metonymy**).

Paralinguistic Information Paralinguistic descriptions of the source's presumed emotional state, or of his or her manner of speaking may also have an impact on the hearer's evaluation of the source and the reliability of the reported proposition(s). Consider this example: *A downcast Mr. Trimble said that the evidence given to him by the commission was insufficient* (*Daily Telegraph* 11/22/03).

Explicit Evaluations Whereas the above-mentioned evaluations of sources are more or less implicit, explicit evaluations of the source may also be employed as a means of influencing the presumed reliability of reported propositions. Thus, labels with negative or positive connotations (*terrorists, fanatics, resistance fighters*), premodifying adjectives (*callous, racist, intelligent, cultivated*), or other explicit means of

evaluation may be employed in order to credentialize or discredentialize sources.

The Reporting Expression

The other main way of evaluating the reliability of reported propositions is by virtue of the reporting expressions used. The most well-known are reporting verbs such as *say, state, claim*. But there are also reporting nouns (*disclosure, claim*), adjectives (*alleged, reported*) and prepositions (*according to*). Such expressions may communicate degrees of speaker agreement, as well as positive and negative evaluations.

Degrees of Speaker Agreement As has often been pointed out, reporting expressions may be neutral as to whether the speaker agrees with the reported proposition (*say, write*), positive/supporting (*X has rightly pointed out, proven, shown*) or negative/skeptical (*claim, pretend*) (Hunston, 2000; Thompson and Ye, 1991). By varying their use of such reporting expressions, speakers can again try to influence the hearers' perception of the reported proposition.

Positive and Negative Evaluations Like descriptions of sources, certain reporting expressions can also (more or less) explicitly trigger hearers' evaluations. Clayman (1990) has shown that the use of reporting verbs that refer to the discourse process invites hearers to make evaluative inferences about sources. Verbs such as *concede, admit*, for example, can imply that the source did not speak voluntarily and may prompt hearers to ask why; verbs such as *refuse, decline* indicate that the source did not in fact answer a question and may again prompt hearers to ask why. Similarly, illocutionary verbs that do not refer to the discourse process may be employed for purposes of evaluation. Whether someone *quips, jokes* and *promises* or *threatens, mocks* and *vows* can crucially influence hearers' interpretations. Combinations with adverbs can enhance or neutralize negative reporting expressions (*he reluctantly admitted that* vs. *he frankly admitted that*). At the more explicit cline of evaluation, we can posit the use of reporting expressions that are almost unequivocally evaluated as negative (*boast, brag*). In making explicit the illocutionary force of speech acts, speakers thus signal their own evaluative stance toward the reported discourse and may predispose readers' interpretation (Fairclough, 1988). (Of course, even if the reporter faithfully reports the illocution of the speaker's utterance, the act is merely mentioned, not performed.) (see **Speech Acts**).

The Reported Proposition(s)

The last component of reported speech discussed is the reported proposition, with a focus on the different types of reported speech (i.e., direct speech, indirect speech, etc., and narrative reports of speech acts as distinguished by Leech and Short, 1981). Besides serving as résumés, abstracts, or conclusions of the reported speech, these types fulfill a gamut of pragmatic functions. Direct speech is generally regarded as highly reliable, because it purports to report the original speaker's actual choice of words, and hence functions pragmatically to lend reliability to the discourse (except when used as an expression of irony or "mocking mimicry"; Haiman, 1995). Indirect speech, on the other hand, does not claim to represent the original speaker's actual use of lexicogrammar, focusing on the ideational rather than the interpersonal meaning of reported propositions (see **Systemic Theory**). In spoken discourse, indirect speech is therefore often employed to clarify, to provide clear factual information to hearers (Mayes, 1990). In fiction, the "loss of . . . vivid, colloquial, partisan and engaged lexis" renders the narration "more 'neutral' and formal" (Toolan, 2001), resulting in greater distance between the reader and the characters. In free indirect speech the voices of the original speaker and the reporter are not as clearly demarcated as in direct speech: the two levels of discourse are merged (Fairclough, 1988) (see **Literary Pragmatics**). Consequently, free indirect speech (FID) is a powerful instrument in mystifying what could be called, with an allusion to Goffman, principalship (Fairclough, 1988) (see **Goffman, Erving**). In fiction, FID is a characteristic of modernist stream-of-consciousness writing and serves a "strategy of . . . alignment, in words, values and perspective, of the narrator with a character" (Toolan, 2001), which may convey the speaker's irony or empathy (Toolan, 2001; Leech and Short, 1981). Narrative reports of speech acts, finally, may be regarded as the most evaluative, in that they consist wholly of the speaker's interpretation of an utterance or utterances she or he has heard. Since the speaker reports the occurrence of a speech act without mentioning its meaning, hearers have no possibility whatsoever to double-check the reporter's interpretation of the original speaker's words.

Social Functions

The choice of reported speech can be a means of establishing, maintaining, and securing social relations. By deciding what to report and how to report it, the reporter indicates different degrees of

evaluative and social closeness or distance, of familiarity and formality, of politeness and respect (see **Politeness**). This may be achieved by verbal (including prosodic) and also nonverbal means (gestures, mimics, etc.), which originate with the reporter or else accompany the reported utterance (see **Gestures, Pragmatic Aspects**). (Rather than using *verba dicendi et sentiendi*, verbs related to 'body language' as in *She frowned/shrugged/smiled: '...'* can be used.).

Textual Functions

Regarding textual functions, direct quotations can be used to dramatize and highlight important elements in a narrative (Mayes, 1990; Fairclough, 1988). In fiction, they are associated with a "scenic showing of pace, enhanced focus on the specificity and detail of an interaction" (Toolan, 2001), in short, "vivid and engaging" (Toolan, 2001) narration. Indirect speech seems less vivid and colorful, and narrative reports of speech acts appear to be often used when speakers do not want to transmit the actual words of the reported speaker, e.g., for purposes of abridging and summarizing.

Future Research

Many aspects of the pragmatics of reporting speech allow room for future research. A starting point could be the exploration of cross-cultural as well as genre-specific differences. Further research could investigate the connection between reporting speech and reporting thought as well as the relation between reported speech and notions such as evidentiality (Chafe and Nichols, 1986), commitment (Stubbs, 1986) and evaluation (Thompson and Ye, 1991).

Rhetoric: History

J J Murphy, University of California at Davis, Davis, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Rhetoric is the systematic analysis of human discourse for the purpose of identifying useful precepts for future discourse. Since it deals with human thought and expression, it has been linked through the centuries with psychology, philosophy, ethics (both private and public), and education.

Aristotle's Rhetoric

Rhetoric originated in ancient Greece, primarily in Athens, and was connected with a rising democracy that placed a premium on the speaking ability of each individual citizen. Even the philosopher Plato wrote on rhetoric, notably in his *Phaedrus*. The first major effort at a comprehensive theory of public speaking, however, was made by Aristotle in his *Rhetoric* (before 322 B.C.E.). He defined rhetoric as the faculty of observing in any given case the available means of persuasion. Aristotle named three types of orations: political, forensic, and epideictic (occasional). He declared that the object of rhetoric, persuasion, is achieved through the use of three 'proofs': *ethos*, the credibility of the speaker; *pathos*, the emotions of the audience; and *logos*, the arguments used. The main types of arguments are the example and the enthymeme, a rhetorical

syllogism; Aristotle provided 28 sample 'topics' or lines of argument on which enthymemes can be based. He began Book Three by stating that it is not enough to know what to say; the speaker must also know how to say it. The subsequent discussion of style noted that the foundation of good style is correctness of language; at the same time Aristotle called for 'distinctiveness' of language, achieved through use of such devices as metaphors.

Interestingly, Aristotle's *Rhetoric* had very little influence in antiquity or the Middle Ages, becoming influential only after its translation into Latin in 1475 in Renaissance Italy.

Roman Rhetoric

Aristotle died in 322 B.C.E. We know very little about the development of rhetorical theory between that date and the emergence of a homogenous set of rhetorical doctrines shortly after 100 B.C.E. Though these ideas are embodied in his *De inventione* and six other rhetorical works of Marcus Tullius Cicero (105–43 B.C.E.), in the anonymous *Rhetorica ad Herennium* (c. 87 B.C.E.), and in the *Institutio oratoria* (95 C.E.) of Marcus Fabius Quintilianus, the concepts are so similar in all these works that it seems fair to describe this common body of rhetorical doctrine as a 'Roman' rhetoric. It laid out five 'parts of rhetoric': (1) invention, the discovery of valid or seemingly valid arguments that render one's case plausible; (2) arrangement, the distribution of these arguments

in a proper order; (3) style, the fitting of the proper language to the invented matter; (4) memory, the firm mental grasp of matter and words; and (5) delivery, the control of voice and body in a suitable manner. This theory of 'five parts' dominated Western rhetoric at least until the early 20th century and is still important today; its longevity is due at least in part to the fact that it is a natural progression of composition.

Roman invention included both 'topics' (as in Aristotle) and 'issues' or the points to be resolved in a controversy. In arrangement, the Romans specified a sequence of six parts of the oration itself: introduction, narration of background, partition (or outline of the case), confirmation, refutation, and peroration (conclusion). Style is identified under three levels – plain, middle, and grand – with distinction (*dignitas*) to be achieved through the use of 'figures.' Book Four of the *Rhetorica ad Herennium* is the first to name 64 figures, divided into figures of speech and figures of thought, that were to become a standard for nearly two millennia; 10 of the figures of speech (e.g., metaphor, metonymy) later went under the name of 'Tropes.' So dominant was this set that this fourth book was often copied separately in the Middle Ages and Renaissance. The *Rhetorica ad Herennium* is also the first rhetorical treatise to offer a section on memory, involving the use of mental backgrounds into which mental images of remembered things can be placed. Delivery calls for the speaker's regulation of his voice, facial expression, and gestures.

The Roman educator Quintilian in his *Institutio oratoria* (95 C.E.) not only reinforced all these doctrines but outlined a systematic training program in grammar, literature, and rhetoric that set an educational standard followed for nearly 2000 years in Europe and America.

By the end of the classical period, then, a large number of sophisticated rhetorical concepts had been identified and combined into a well-coordinated, effective Roman system. In fact, some modern scholars, such as Brian Vickers and George A. Kennedy, evaluate later rhetorical developments according to the rate at which they accord with classical rhetoric.

Medieval Rhetoric

The Roman concept of 'seven liberal arts' – which included the subjects of grammar, rhetoric, and dialectic – was introduced into the Middle Ages by encyclopedists such as Martianus Capella, Isidore of Seville, and Cassiodorus. These encyclopedists offered highly condensed abstracts of rhetorical lore, usually without examples. They were, however, a main

source of knowledge about rhetoric for many in the Middle Ages. The copying of Ciceronian rhetorical texts, especially his *De inventione* and the anonymous *Rhetorica ad Herennium* generally ascribed to him, continued throughout the Middle Ages; these were often accompanied by glosses or commentaries – usually a sign that the texts were used for teaching in schools. It is important to note that during the Middle Ages, rhetoric was taught in what we would call secondary schools, rather than in universities.

Aristotle's *Rhetoric* was copied often in Latin translation, but not used as a rhetoric text; instead it was typically included in manuscript collections on moral philosophy.

The original rhetorical treatises composed during the Middle Ages fall into three categories, each a separate rhetorical genre. The first, developed in the 11th century, was the *ars dictaminis*, or art of letter-writing. Basically this art took the Ciceronian pattern of six parts of an oration and set up a five-part format for writing a letter: salutation (based on the social level of writer and addressee), introduction, narration, petition, and conclusion. Many of the 300 surviving dictaminal manuscripts are accompanied by model letters. All are in Latin. The second genre, the *ars poetriae* or art of writing poetry, was in teaching practice, the art of writing both verse and prose. The *Poetria nova* (c. 1210) of Geoffrey of Vinsauf was the most important of the six major Latin works that appeared between 1170 and 1280. Relying heavily on the *Rhetorica ad Herennium*, including the use of all 64 figures from the fourth book of that text, Vinsauf laid out a Ciceronian pattern for the composition of verse and prose. The fact that it survives in 200 manuscripts indicates that the book was enormously popular. It is important to note that in the Middle Ages poetry (and some prose) was meant to be read aloud, so the application of Ciceronian rhetorical principles to poetry was not as unusual as it might seem to modern readers. All the authors of the *ars poetriae* were grammarians, and in fact one of them, John of Garland in his *De arte prosayca, metrica et rithmica* (after 1229), tried to establish a linguistic base for all language use.

The third medieval rhetorical genre was the *ars praedicandi*, or art of preaching.

The medieval oral sermon shared some of the characteristics of the ancient oration, but the circumstances were quite different. Persuasion was not the objective, since the congregation consisted of people already committed to Christianity. Consequently, the emphasis was on explanation and reminders of the text of the Bible. More than 300 separate 'arts of preaching' appeared between approximately 1200 and 1500, following a basic format of elaborating on

a 'theme' (usually a passage from Scripture). The theme was divided into parts (usually three), each part was then redivided, and each of these parts was 'amplified' and or 'proved' in a variety of ways. Some commonly used means of amplification were the exemplum (narrative example), authority, reasoning, etymology, allegory, and metaphor. Despite the oral nature of the sermon, the treatises seldom discuss delivery.

The Renaissance

Two factors led to an explosion of interest in rhetoric in early modern Europe. One was the recovery of all the ancient rhetorical works of Greece and Rome, most of which had not been known during the Middle Ages. For example, the complete text of Quintilian's *Institutes of oratory* was discovered in Switzerland in 1417, and Greek texts were brought to Italy from places such as Constantinople for study by humanist scholars.

The other factor was the advent of printing. A staggering number of rhetoric texts were printed between 1465 and 1700: Lawrence D. Green and James J. Murphy have identified 3842 titles by 1717 named authors and 120 anonymous authors, produced in 310 printing towns by 3340 printers and publishers.

It is obviously impossible to summarize all the developments during this period, but some important features are the application of classical rhetoric to preaching, the attack of the new empirical science on the epistemological assumptions of classical rhetoric, the rise of 'general rhetoric' (an amalgam of Greek and Roman sources), and the gradual democratizing of rhetoric from an elite Latin to a popular vernacular art. One particular development, though, is important enough to note. The French university master Peter Ramus, following the lead of Rudolph Agricola's work on logic, declared in 1543 that Aristotle, Cicero, and Quintilian were all wrong about rhetoric. He assigned Invention and Arrangement to dialectic, leaving only Style and Delivery to rhetoric (and leaving Memory out as a separate part). Ramus was immensely popular, especially in Protestant countries, and had great influence in colonial America as well. Walter J. Ong has calculated that 1400 editions of his and his followers' works were printed. The resulting controversy between Ramists and Cicero-nians lasted well into the next century.

Modern Rhetoric

Since 1700, rhetoric has gone from being an integral part of education and civic life to an ignored or even

opposed entity today. Some even believe that rhetoric today is so diluted in its efforts to be all-encompassing that it is difficult to identify the core of the subject. But there has been no single climactic event to which this change can be assigned. Of course, there have been many variations of basic rhetorical theories and there have been differences in emphasis on one part of rhetoric or another. For example, the so-called 'elocutionary movement' of the 18th century in works by authors such as Thomas Sheridan and Gilbert Austin focused on pronunciation and other aspects of delivery. The Scotsman George Campbell argued in his *Philosophy of rhetoric* that to achieve persuasion rhetoric must address four 'faculties' of the mind – the understanding, the imagination, the passions, and the will; he also declares scientific linguistics to be the foundation of rhetoric. The 'belletristic movement' linked rhetoric, literature, and 'taste,' as marked in books such as the influential *Lectures on rhetoric and belles lettres* (1793) of the Scotsman Hugh Blair. Another Scottish development, linked to growing demands for socially advancing education, was the application of rhetoric to writing – a movement that was to affect pedagogy in the United States. The 19th century philosopher Friedrich Nietzsche declared that language is rhetoric, because it can express only opinion, not knowledge; consequently 'truth' can be seen as a linguistic social agreement rather than objective fact. In the opinion of rhetorical historians Patricia Bizzell and Bruce Herzberg, Nietzsche anticipates themes developed by 20th-century rhetoricians such as I. A. Richards, Richard Weaver, and Chaim Perelman, as well as philosophers Michael Foucault and Jacques Derrida. Finally, the application of the methods of social science to discourse analysis in recent years has produced a field of 'communication' markedly different from a rhetoric relying on thought and on perceptions by individuals.

At the beginning of the 21st century, then, rhetoric is like the multistream delta of a long river that spreads its central channel into a variety of channels. This is perhaps, not surprising, after such a long history.

Rhetoric: Semiotic Approaches

Introduction

‘Rhetorics’ is a polysemic word. All the meanings connected with it fall into two major groups: in the first one, rhetorics is regarded in a narrower and more traditional sense, in relation to verbal texts; in the second one, rhetorics is treated in a more universal and modern sense, in relation to expressing any information (e.g., visual rhetorics). It is nevertheless clear in both cases that rhetorics operates with signs and therefore fits completely into the framework of semi-otics. Consequently, we could regard rhetorics simply as part of semiotics and semiotics as the ground for rhetorics. On the other hand, Charles Sanders Peirce distinguished three aspects of semiotics (Peirce identified semiotics with logic): speculative grammar, speculative critic, and speculative rhetoric (Peirce, 2.93). Thus, it is rhetorics rather than semiotics that proves to be a more general and basic knowledge. Attention needs to be drawn to the dangers of terminological amorphousness resulting from the nondistinction of rhetorics and metarhetorics; in order to avoid this, we will further speak of rhetoric phenomena when we refer to the object level,

and of rhetorical phenomena when we refer to the metalevel.

Different treatments of rhetorics within the semiotic framework complicate the matter even more, since there is no clarity even in the approaches, not to mention the basic concepts. The researchers proceeding from the Peircean tradition drew attention to the fact that the most important tropes – metaphor and metonymy – are clearly related to the **iconical** and **indexical** signs (Jakobson, 1956, 1980; Shapiro and Shapiro, 1976). Saussure’s disciples, on the other hand, used the concepts and methods of structural linguistics and text grammatics to describe rhetoric phenomena, which gave rise to different directions of structural rhetorics (e.g., Dubois *et al.*, 1970), as well as to deconstructional rhetorics, which was in clear opposition with both traditional and structural rhetorics (e.g., de Man, 1986). An entirely different approach to certain rhetoric phenomena (above all, metaphor and irony) developed within the framework of analytical philosophy (cf. Searle, 1979); from the cognitive linguistics evolved the “everyday rhetorics” (Lakoff and Johnson, 1980). To this, Paul Ricoeur’s hermeneutical approach to metaphor (Ricoeur, 1975) and a whole range of *ad hoc* linguistic, philosophical, and poetical treatments of different tropes and figures should be added. Some approaches focus on the rhetoric structure of the text; others

focus on characterizing different styles, movements, or genres; yet others, on describing different figures and tropes (primarily metaphor) or on solving problems related to the transfer of meaning, etc. At first sight, all this presents an ambiguous picture of the landscape of contemporary rhetorics.

Before we discuss the semiotic aspects of rhetorics, it is necessary to determine what rhetorics is as a whole – or, to be more specific, what is the field where the phenomenon of rhetorics emerges – and second, how and to what extent the semiotical analysis could approach it.

Ancient Rhetorics

Human nature is universal: in different cultures independently of one another evolves congeneric knowledge related to astronomy, geometry, physics, medicine, etc. The existence of linguistic and poetic doctrines is also rather universal. Against this background, rhetorics has an unusual history: it originated in the specific settings of the Ancient Greek civilization, and all the subsequent rhetorical schools and traditions have derived from this source. No other ancient culture has developed anything that could be likened to classical rhetorics. This fact is even more remarkable as rhetorical matter is unspecific: all rhetoric phenomena can be entirely distributed among grammar, stylistics, poetics, and logic. Thus, most *rhetoric figures* and *tropes* have analogues in Persian, Arabic, Indian, as well as Chinese poetical traditions. Moreover, for instance Aristotle, within the Greek tradition itself, discusses the same phenomena in his *Rhetorics* and *Poetics*. The differences between these lie not in the matter but in the purpose: the aim of the poetic text is catharsis; that of the rhetoric text, to convince a listener.

The specific setting that made possible the rise of rhetorics in the European civilization involved the liberation from tyranny and the establishment of democracy in Athens and the restoration of usurped land to its legal owners. In a culture with no written ownership acts, the oral public word became the main tool in the settlement of disputes, and, above all, legal disputes. Rhetorics as an art of speech grew out of the practical needs of democratic institutions (republic, public political competition, freedom of speech, public justice); court and political speeches became the most important rhetoric genres.

Of course, Greek culture was not the only one where the art of public speech was fostered: Japanese, Chinese, and Muslim cultures present remarkable examples of this kind. Nevertheless, the corresponding fields cannot be really compared to ancient rhetorics, as in their case we are rather dealing

with poetics, speech etiquette, etc. Rhetorics needs freedom and competitive public debate in the condition of equality of debate partners; speakers enter the contest where their only resources and weaponry are words and the skill of using them.

Even those schools of rhetoric that were primarily oriented toward ornamental style (the Asian school) – or those that claimed, similarly to Gorgias and in the spirit of Sophists, that they could prove anything – pursued the right influence of speech, i.e., they proceeded not from the semantic but from the pragmatic notion of truth. Thus, Gorgias compares his speeches to *phármakon* ('drug') that a speaker uses to take his listener to a desired state of mind. In any case, ancient speech practice usually regarded ornaments as tools, not as an aim *per se*. It is informative to compare Greek rhetorics with Sanskrit poetics, since both evolved from the same Indo-European tradition. In the older stratum of the Sanskrit poetics (which has been preserved in Bhamahā's and Dandi's treatises of the 7th and 8th centuries) the central concept is *alankara* ('ornament'), which is comparable to the Greek *schema* ('figure'). The aesthetics of *alankaras* is very simple: the more ornaments there are and the more complex the constructions they form, the higher is the aesthetical value of an utterance. The later Indian tradition focused on the concept of *dhvani* (Anandavardhana's *Dhvanyaloka*, 9th century), which is not easy to translate: it is a hidden image, not expressed through words. Although the mechanistic doctrine of *alankaras* differs radically from the spiritualistic teaching of *dhvani*, both are entirely different from the Greek concept of rhetorics, where *schemata* do not have a sovereign value and every meaning can be expressed through word.

As it became an independent discipline, rhetorics had to define and position itself in relation to other branches of learning. Rhetorics opposed poetics as a skill of verbalizing real events against the skill of verbalizing fictional events; rhetorics opposed dialectics as an art of monological speech against the art of dialogue; rhetorics opposed logic as an art of expressing one's thoughts against the art of thinking (according to Aristotle, rhetorics is something like applied logic; logic which uses syllogisms is an art of proving, rhetoric is an art of persuasion, instead of syllogism it uses *sorites* consisting of *enthymemata*), etc. Already by the 5th century B.C., there had emerged an intuitive notion of truth that could be termed the *rhetorical ideal*. According to this ideal, thinking, speaking, and acting form an inseparable complex: it is possible for a human being to develop and formulate his or her thoughts and ideas properly (the sphere of logic), to express them properly (rhetorics), and, in

accordance with these, to act properly (justice). In the Roman Republic, rhetorics became even more connected with truth and justice; i.e., Cicero treated such ‘hermeneutical’ problems like the use of torture during the interrogation. Rhetorical ideal, which provided a foundation for the European mentality, prevailed at least until the 18th century and applies to some extent today. The rhetorical ideal was based on the intuition that the road to truth is the straightest of all possible roads and has to be followed in one’s thoughts, words, and actions. An outstanding 17th-century pedagogue, Jan Amos Komensky, started his treatise *Orbis sensualium pictus* (1658), which was intended to be a textbook, with a definition of wisdom: “*recte intellegere, recte agere, recte eloqui*” (“to comprehend properly, to act properly, to speak properly”). It is important to emphasize that an initial conception of rhetorics treated it as the art of speaking the truth.

Classical rhetorics consisted of five subdivisions: (1) invention (*heuresis, inventio*), (2) arrangement (*taxis, dispositio*), (3) style (*lexis, elocutio*), (4) memory (*mneme, memoria*), (5) delivery (*hypokrisis, pronuntiatio*). These subdivisions formed a logical whole, but at the same time their sequence marked an ideal succession of rhetoric activities that corresponded to the rhetorical ideal: the logical sequence expresses itself on the operational level.

During the Roman Empire, public speech lost its social role related to the seeking and expressing of truth. This diminished greatly the relevance of the first and, to a large extent, the second subdivision. The spread of the written word reduced the importance of also the fifth and especially the fourth subdivision. In contrast, the significance of the third subdivision had been increasing since the Hellenistic period. In the Middle Ages, the field of rhetorics was divided in two: the first, speculative rhetorics, became essentially a part of scholastic philosophy, which focused on the classifications of figures and tropes. As a practical oratory, rhetorics retained its relevance in sermons, forming the sphere of homiletics.

At the same time, already in the late antiquity but especially in the Middle Ages, rhetorics started to interfere with poetics, above all with regard to written texts. Rhetorics became the teaching of prose. It is interesting that even Dante and Petrarca in their Italian prose attempted to follow instructions for *cadentia* at the ends of periods. Consequently, at least for the early humanists, the Latin speech rhythm codified by Cicero became the general principle of style for written language. The decline of scholastic philosophy and the secularization of culture inevitably led to the crisis of rhetorics.

The first criticism of rhetorics evolved in the context of rationalism and especially of the philosophy of enlightenment. The crisis of rhetorics was inseparably connected with the crisis of (Aristotelian) logic. For instance, in Molière’s play *The would-be gentleman* (1670), the teacher of logic and rhetorics is presented as a charlatan. For Molière, Rousseau, and others, rhetorics came to mean the art of lying; truth required no skills. Interestingly enough, the crisis of rhetorics stemmed also from the rhetorical ideal (the purpose of speech is to approach the truth); only the notion of rhetorics changed: it was now regarded as an art of evasion.

The rhetorical ideal survived the classical rhetorics; we can come across its reflexes in the modern Western civilization in such different spheres as analytical philosophy, which advanced the notion that telling the truth is a simpler and more logical way of speaking than lying, and the assessment of utterances with the help of a lie detector, a practice based on the presumption that the organism of a lying person undergoes psychosomatic changes.

Ancient Semiotics and Rhetorics

Although the first treatise devoted to semiotics – *Cratylus* by Plato – had by the 5th century B.C. already been written, semiotics as a discipline and even the word ‘semiotics’ was then unfamiliar. In antiquity, rhetorics as a branch of knowledge was not related to the semiotics of that time. *Cratylus* focused on the problem of the motivation of sign without relating this to the art of speech. In *Phaedrus* we encounter both semiotical and rhetorical issues, but these were not brought together.

Probably the first to use the term ‘semiotics’ was a doctor and medical theoretician, the developer of the Hippocratic tradition Galen (2nd century A.D.); he employed it to refer to symptomatology – in modern terms, diagnostics. It should be emphasized that such treatment of semiotics has no connection with rhetorics. Ancient (medical) semiotics belongs to the sphere of what Carlo Ginzburg calls “the evidential paradigm.”

It could be said that this paradigm is in direct opposition to the spirit of rhetorics: the basis of rhetorics is the skill of speaking the truth and a notion that truth is simple and logical, while telling the truth can be governed by *a priori* fixed rules; semiotics, on the other hand, studies indirect signs to find out the unsaid truth and takes roundabout routes – one and the same disease can have different symptoms.

To modern semiotics, however, rhetorics is the closest of all the ancient spheres of knowledge. Many problems of contemporary semiotics (denotation,

the relationship between name and description, etc.) found their first treatment precisely in ancient rhetorics. In addition, there are clear correlations between the principal dimensions of semiotics and the main subdivisions of classical rhetorics: the syntactical approach reveals itself in arrangement and partially also in style; the semantical approach can be observed both in invention and in style – in the case of invention, we are dealing with strong, referential semantics; in the case of style, with weak, significative semantics; the pragmatic approach manifests itself in memory and pronunciation.

Structural Rhetorics

The crisis of rhetorics lasted until the middle of the 20th century, when structural linguistics rediscovered tropes and figures. A central figure of structural rhetorics was Roman Jakobson, who linked different tropes with art forms and schools on the one hand and with different cognitive processes on the other hand. These phenomena had never before been related to rhetorics, which therefore meant a substantial expansion of the field of rhetorics; at the same time, Jakobson reduced the whole subject matter of rhetorics to two tropes, metaphor and metonymy, and treated these as universal semiotic mechanisms. Metaphor is the basis for the mechanisms of romanticism and poetry; metonymy, for that of realism and prose. According to Jakobson, the grounds for metaphor and metonymy could be found in the structure of natural language, in its two axes. The axis of combination (syntagmatics, in Jakobson's words) was the basis of metonymical relations; the axis of selection (paradigmatics), that of metaphorical relations. Since according to Jakobson the mechanism of poetry lay in the projection from the axis of selection onto the axis of combination – which led to the organization of sequences in verse according to the principle of equivalence – it is clear why verse is dominated by metaphor. However, in the case of prose, we are dealing with pure sequence, which creates a basis for the predominance of metonymy.

All this, in turn, correlates on the one hand with the difference between visual and acoustic signs and on the other with the functional asymmetry of the brain. Comparing fine arts and music, Jakobson called attention to the fact that the first is governed mostly by the principle of iconicity – i.e., the signifier is motivated by the signified, and so-called abstract art based on arbitrary signs is always problematic. At the same time, in music the situation is reversed: music employs predominantly arbitrary signs or symbols, and so-called concrete music based on icons (e.g., the sound of a cuckoo) and indexes (e.g., the whistle

of a train as a sign of journey) – even if it does not cause displeasure – is clearly a different kind of music. Jakobson concludes that visual and acoustic information differ in principle: for some reason our eyes prefer to trust icons, but our ears tend to trust symbols. Visual signs represent space, and the principles of space are symmetry and similarity – i.e., equivalence. Acoustic signs represent time; their principle is sequence. Again, all this is related to the functional asymmetry of the brain. The subdominant (usually right) hemisphere is oriented toward visual information and its metaphorical treatment; although the prevailing sign type is icon, indexes belong to this sphere as well. The dominant (usually left) hemisphere is oriented toward acoustical information, metonymy; the prevailing sign type is symbol.

Yuri Lotman drew on Jakobson's approach but made some important additions and elaborations. First of all, Lotman argued that the sphere of rhetorics cannot come into being on the basis of only one (e.g., natural) language: rhetoric phenomena emerge when at least two semiotically different languages collide. Already the basic concepts of rhetorics – 'image,' 'figure,' etc. – have clear connotations of the visual sphere. Lotman drew attention to the fact that a large number of metaphors are related to the visual semantics, but visuality alone is not sufficient: visual information has to be transmitted by verbal means. Thus, metaphor is a translation from the language operating with visual signs into the verbal language. These languages have different semiotic statuses: visual codes are mimetic, are founded on iconicity, and are continual, while verbal codes are discursive, are discrete, and are founded on symbolism. Even when a metaphor or a metaphorical epithet is not related to a visual image (e.g., 'sweet dreams'), we are still dealing with the recoding of iconic information by means of symbols. The above is characteristic of the traditional sphere of rhetorics, but Lotman recognized the possibility of a reverse situation as well: information encoded with a symbolic code can be transmitted through an iconic code. This way visual symbols are formed, and here too we can speak of different tropes – e.g., visual metaphor and metonymy. While verbal images come into being through the transmitting of visual messages by verbal means, visual images emerge through the transmitting of verbal messages by visual means.

Structural Rhetorics and Text Theory

Independently of Jakobson, but simultaneously with his work of solving rhetorical problems with the help of modern linguistic and semiotic methods, the peripheral areas of linguistics developed a contact with topics that traditionally belonged to the sphere

of rhetorics. As late as the middle of the 20th century, linguistics still considered the sentence to be the maximum unit of language (Émile Benveniste even presented special arguments in favor of this view). But by 1952, Zellig S. Harris demonstrated that syntactic relations between constituents cross the sentence boundaries. From this observation evolved text linguistics, one of the leading areas of linguistics during the years 1970–1980. Within the field of text linguistics, different tendencies can be discerned. There were authors who, in the spirit of Harris, confined themselves to purely formal textual parameters, such as (a) anaphoric repetitions (in contrast to classical rhetorics, which held that anaphora could occur only at the beginning of a colon or a period, text linguistics understood anaphora in a much wider sense: as any lexical repetitions in different syntactic sections); (b) substitution of lexemes with pronouns in consecutive sentences; (c) grammatical restraints that exceed sentence boundaries (Gasparov, 1971). Other authors examined syntactic relations between sentences in a wider semantic and pragmatic context (Van Dijk, 1972, 1981). Pragmatic aspects come in, in connection with describing the communicative structure of the relations between sentences.

It has been observed that sentences join into a coherent text according to a certain rule: what is the rheme in a previous sentence becomes the theme in the next. In contrast to Harris, who operated mainly with the terms of sentence structure, in such an approach the main element becomes text as a communicative whole. Although text theorists seldom refer to classical rhetorics, they deal with similar problems. The structure of a coherent text is based on repetitions on different levels, and the majority of rhetoric figures and tropes (anaphora, epistrophe, symple, alliteration, parallelism, antithesis, simile, etc.) follow the same principle. When we look at a text as a whole, we can see that the use of tropes forms a definite system in the text. For example, if a text contains many metaphors, it is likely to also have plenty of similes and epithets. If metonymies prevail, synecdoche and irony tend to appear frequently as well.

The Semantic Foundations of Structural Rhetorics

Already Roman Jakobson in his study of tropes paid close attention, in the spirit of the Prague Linguistic Circle, to semantic elements smaller than words. This made it possible for us to be considerably more specific than the ancient teaching of tropes as figures of thought. For example, when we speak of transferred meaning in the case of metaphors, it is clear

that what is transferred is not the whole meaning of the word but only a part of it. Different models of structural rhetorics approached the problem of the figurative meaning differently. For instance, if we proceed from the concept of semantic fields, we can represent meaning as space in the topological sense. In such a case, metaphor can be described as an intersection of two semantic fields, and the more distant the meanings are, the stronger the effect of the metaphor is. Greater influence, however, was gained by an approach based on the componential analysis of meaning. If we picture the meaning of a word as a matrix of markers and distinctors (to use the terms of Jerrold J. Katz and Jerry A. Fodor), the metaphorical expressions can be described as constructions where the *vehicle* projects one or several of his markers onto the *tenor*.

An important role in the description of language-semantic mechanisms of metaphor has been played by Uriel Weinreich (1966). He demonstrated that semantic syntax is not based on only one operation (as Katz and Fodor assumed), an operation that could be called “linking of meanings,” but that there exists at least one more relationship – ‘nesting,’ in Weinreich’s vocabulary. Thus, if we represent the meaning of a word in the form of a matrix, we have to accept the possibility that the matrix contains another matrix as its component. In addition, he argued that rules of semantic syntax could be formulated more effectively if we assumed that the matrices of meaning might contain lacunae in which the components of meaning could be nested. Different operations produce different tropes. Linking creates epithets: for instance, linking the meaning ‘ball’ with the component ‘red’ produces the expression ‘red ball.’ However, it must be added that this mechanism characterizes only modern epithets oriented toward creating new information; archaic epithets, on the contrary, are pleonastic, utterly redundant. For instance, in the expression ‘round ball,’ roundness is not linked to the meaning ‘ball’ but instead extracted from it. Metaphor, on the other hand, is created as a result of nesting. Unlike Katz and Fodor, Weinreich does not regard expressions like “a rock is dreaming” as having a conflict in semantic syntax: ‘rock’ [– *alive*] cannot be joined to ‘dreaming’ [+ *alive*]; ‘dreaming’ is nested in ‘rock.’ A classification of different rhetoric tropes and figures deriving from componential analysis was proposed by Groupe μ (Dubois *et al.*, 1970).

Pragmatic Rhetorics

The various branches of structural rhetorics differed substantially in their purposes from the classical

rhetorics. All of the new branches are occupied with the structure of text, not its effect, and therefore the approaches of both Roman Jakobson and Groupe μ pertained more to the field of poetics than to that of rhetorics. Speech act theory, together with the adjacent fields, can be regarded as an attempt to revive, with the tools of modern philosophy, the rhetorical ideal, according to which *plan*, *construction*, and *activity* form an inseparable unity and at the same time a natural sequence. John L. Austin, regarding language activity, joins the first two (plan and construction) under the name “locutionary speech act,” names the third one (action) “illocutionary act,” and adds to these *consequence*, under the name “perlocutionary act.” (Classical rhetorics was not concerned with the effect of speeches, but it is clear that the principle of perlocutionarity derives from the spirit of rhetorics, which regards speech as a responsible activity.) For example, John Searle’s discussion of metaphor from the perspective of speech act theory represented the return of the aims of classical rhetorics. At the same time, in comparison with that of classical rhetorics, Searle’s approach was clearly much more limited – of all the tropes and figures, he paid attention only to metaphor and irony (it has often been questioned whether the latter should be regarded as a trope at all).

Searle’s approach was above all characterized by his position that metaphor is not a figure of thought obtained by the joining of words but rather an utterance. Furthermore, Searle argued that such a phenomenon as figurative meaning does not and cannot exist at all: words and sentences mean what they mean. The phenomenon of metaphoricality emerges not in words but in their use and, hence, not in the field of semantics but in pragmatics. Searle proposed the following hierarchy: direct speech acts, indirect speech acts, metaphor, irony. Metaphor emerges when the sentence meaning diverges from the utterance meaning. Searle distinguished between simple and complex metaphors: in the first case, the relationship between a sentence and an utterance is one-to-one; in the second case, several utterances correspond to one sentence. However, in both cases the utterance meaning can be inferred from the sentence meaning.

The rhetorics based on the speech act theory is the complete opposite of George Lakoff and Mark Johnson’s “everyday rhetorics”: whereas Searle accepted only the literary meaning, for Lakoff and Johnson the figurative word use was basic. Lakoff and Johnson’s approach resolutely dismissed the traditional teaching of metaphor, which rested on an assumption that there exists a neutral, nonfigurative speech that an author embellishes with figures and tropes. They pointed

out that there is no such thing as a neutral, nonmetaphoric background in language: common speech is full of metaphors, but speakers and listeners usually do not notice them, since they live by them. Lakoff and Johnson demonstrated that metaphors are not accidental semantic curiosities; rather, they have a systemic nature that has a great influence on the speakers’ worldview. One of Lakoff and Johnson’s examples concerned speech activity. The metaphorical expression “argument is war” forms an entire linguo-cultural paradigm that treats different aspects of argument in terms of warfare. Although it seems that the relationship between the approaches of Searle and of Lakoff-Johnson is antagonistic, they complement each other substantially. Speaking cannot be totally controlled by reason and entirely imposed by discourse and culture. The processes described by Searle and Lakoff-Johnson form two opposite poles in the continuum of speech activity. The Russian philosopher Mikhail Bakhtin raised an analogical problem in his work *Toward a philosophy of the act* (1919–1924), Bakhtin’s doctrine was named the rhetoric of act. Act is not any deed, but only a meaningful and responsible one – i.e., it changes *status quo*, and an agent takes a full responsibility for it. The speech act theory is very close to Bakhtin’s views.

Rhetorics and Semiotics of Culture

From the viewpoint of the semiotics of culture, two levels of rhetorics should be distinguished: implicit rhetorics as a strategy of generating texts (on this level, rhetorics is a cultural universal), and explicit rhetorics (or rhetorics in the direct sense of the word) as a teaching of generating texts. The semiotics of culture, especially the semiotics of culture of the Tartu-Moscow school, is characterized by an extended understanding of text: text is a vehicle not only of verbal but of any kind of information; text is a signal that an addresser sends to an addressee, and in the positions of both the sender and receiver, there can appear individuals and social groups as well as whole cultures. In this sense it is possible to regard, for example, ballets, commercials, chess games, election campaigns, and wars as texts. Every such text has its own grammar, stylistics, and rhetorics. From the viewpoint of cultural typology, each culture displays its own clear rhetorical characteristics. The Western European rhetorical ideal is simplicity and straightforwardness, based on Cratylean understanding that things have their right names and speech activity is controlled by reason. It is interesting that although the expression “the beginning of wisdom is to call things by their right names” is attributed to Confucius, in Chinese and in Far Eastern speech practice in

general, there prevail indirect speech strategies and an idea that many different roads lead to truth. Such understanding permeates different strata of culture: for instance, we can see how the rules of rhetorics are reflected in the art of warfare. The metaphor “argument is war,” analyzed by Lakoff and Johnson, is effective in different cultures; at the same time, it reflects the important characteristics of these cultures. While European warfare, which developed from the ancient model, focuses on two main operations – attack and defense – in the Chinese art of warfare, the central role is played by the roundabout maneuver; the highest art of warfare lies not in the battle but in avoiding the battle: “The skillful leader subdues the enemy’s troops without any fighting; he captures their cities without laying siege to them; he overthrows their kingdom without lengthy operations in the field” (Sun Tzu, *The Art of War*). The differences between the Greek and the Chinese arts of war reflect the leading strategies in the speech etiquettes of these cultures. Whereas the Greek orator and military leader both build their argumentation resp. military forces following ideal forms (e.g., in Plato’s case, the ideal for both rhetorics and warfare is geometry) with the aim of destroying the opponent’s argumentation resp. military forces, the Chinese art of war follows the prevailing rule of Chinese speech etiquette, according to which the speaker (especially when the speech is directed to an equal or a superior) cannot express the message explicitly: a speech act is considered successful if the addressee receives the information without the speaker’s having expressed it directly – the problem is solved without a debate (Jullien, 1995).

It would be an extreme oversimplification to link two rhetoric strategies rigidly with geographical parameters of different cultures: we come across both mechanisms in the East as well as in the West; what becomes decisive is their proportion. Even in the context of Western European culture, H. Paul Grice’s maxims of conversation and Searle’s treatment of speech acts should be characterized as a utopian ideal picture that is never achieved in a real communication. Yuri Lotman pointed out that in Europe, different periods are dominated by different rhetoric strategies, but unlike Jakobson, he refrained from straightforwardly associating them with Romanticism and realism. For example, mannerist literature and the speech practices of marginal groups in the era of Romanticism (the parlance of English dandies, the language of French precious ladies, etc.) are clearly oriented toward indirect speech acts, the use of descriptions instead of naming; these are exactly the aspects that attract the attention of a European in the Far Eastern speech etiquette.

Rhetorical Structure Theory

Introduction: What is Rhetorical Structure Theory?

Readers feel that natural texts are coherent and well structured, and that texts achieve rhetorical goals of various kinds. There is also wide agreement that subparts of texts are related to one another in various ways. Understanding these relationships can be seen as an important aspect of having understood a text at all, but linguistic accounts of these uncontroversial phenomena are still limited. Rhetorical Structure Theory (RST) is one of the most significant theoretical and practical advances that has been made in recent times toward making it possible to analyze this kind of structure linguistically. RST seeks to explain the coherence of text by describing how each individual component of a text contributes to the communicative goals of the text as a whole. To do this, RST employs a set of rhetorical relations. These are in principle open-ended, but in practice rather narrowly constrained. An RST analysis, then, progressively deconstructs a text into its smaller component parts. Crucially, because what is being captured is not just a structure but a relationship, each subcomponent itself has (at least) two parts. In every relation, one of the subparts is seen as the most important, or nuclear, component at that level in structure. The other subparts, called satellites, are subservient to the part identified as the nucleus. Each complex of subparts taking part in the relationship is described according to a set of rhetorical relations defined by the theory. A complete analysis then consists of a single hierarchical rhetorical structure defined by rhetorical

dependency links between structural siblings and composition between parts and their subparts. The smallest parts of the structure are called units and correspond directly to portions of the analyzed text.

A text is seen to be coherent and 'well-formed' according to RST when it is possible to construct at least one single overarching hierarchical rhetorical structure for the text as a whole. This structure must obey the organizational principles set out by RST, most important of which are the conditions that RST places on the rhetorical relations that must be used to relate contiguous parts of the text, or text spans. Most natural texts will allow at least one complete analysis. Uncovering that analysis – i.e., making the rhetorical relations involved explicit – can be a significant aid toward understanding how the text achieves the effects that it does.

RST has been used successfully for a variety of tasks, ranging from linguistic text interpretation to computational applications in language production and automatic analysis.

The Origins of RST

RST was originally developed during the mid-to-late 1980s by William C. Mann at the Information Sciences Institute of the University of Southern California (USC/ISI) and Sandra Thompson at the University of California at Santa Barbara. Mann was seeking a model of textual coherence sufficiently explicit to drive automatic text production (see Mann and Moore, 1981) and Thompson had been involved with issues of discourse coherence for many years, particularly researching the textual signals of discourse relations. The concerns of Mann and Thompson were combined in the original formulation of RST. Subsequently, further refinements to the

theory in relation to its links with other kinds of linguistic description were contributed by Christian Matthiessen (then also of USC/ISI).

Mann and Thompson observed that certain sequences of textual material appeared to suggest additional assertions over and above those explicitly made in the text itself (Mann and Thompson, 1986). For example, in the textual sequence in (1), we need to see that the two sentences are related in some way in order to understand why they have been said:

- (1) He explains things well. He'll make a good teacher.

In particular, unless we can see that an additional assertion of the form in (1a) is being made, we will not have understood the text:

- (1a) Because he explains things well, I think he'll make a good teacher.

What we understand in understanding (1) is that the first sentence is being given as evidence for the statement made in the second sentence.

We can readily find sequences where other relations between the parts need to be posited in order to explain the coherence of combinations of linguistic units. For example, in the text extract in (2), we need to posit a relationship of reason between the two sentences.

- (2) The lorry veered off the road. The brakes had failed.

In addition, both of these relationships are quite different from the kind of temporal sequence that we find between sentences in a simple narration. These kinds of relations were identified and catalogued by Mann and Thompson as a move toward understanding how texts 'mean' in addition to the basic or propositional content of the individual sentences, even when there is no explicit linguistic marker of the relation being expressed. These 'implicit assertions' are necessary for both speaker and hearer: a hearer must uncover them in order to understand why sentences are being placed together, and a speaker relies on a hearer uncovering them in order to understand the message.

These kinds of relationships can hold at any level in the text; they are not exclusively relations between individual sentences. This leads to the necessity for a recursive definition of rhetorical structure – that is, text segments in which rhetorical relations of particular kinds are being employed can themselves, as aggregates, take part in rhetorical structures at higher levels. RST does not relate the individual sentences themselves, but the rhetorical intent of the discourse portions over which the rhetorical relations

hold – and this can correspond to individual sentences, units smaller than sentences, and larger units taking in more extensive portions of a text.

Mann and Thompson carried out a detailed examination of the kinds of rhetorical relationships and corresponding rhetorical structures needed to carry out text analysis of texts of any kind. They based this examination initially on a corpus of several hundred texts drawn from a variety of text types. The result was a collection consisting of around 20 relations sufficient for covering the texts they investigated. These relations, now termed classical RST, are set out and defined in detail in several papers, most prominent of which are Mann and Thompson (1986, 1988) and Mann *et al.* (1992). Although Mann and Thompson explicitly stated this list of relations to be open-ended, it has in fact proved very stable over the years. However, occasional evidence has been found for further rhetorical relations that were not included within the original set, and so most researchers now accordingly work with what is called the extended RST set, which now includes around 30 relations. A list of these relations is shown in Table 1.

As intended by Mann, the framework was soon taken up for computational systems, particularly for automatic text generation. The theory has also been taken further by text linguists, who have applied it to a wider range of texts than the original starting point of Mann and Thompson. The extended RST list has also been validated across several languages; contrastive RST analyses have been performed, for example, for Dutch (Abelen *et al.*, 1993), Chinese (Chinese, Mandarin) (Marcu *et al.*, 2000), French, Portuguese, and German (German, Standard) (Delin *et al.*, 1996), Spanish (Taboada, 2004) and a host of

other languages. RST therefore continues to be an active area of research into text organization.

Although primarily developed for the analysis of written texts, there have also been attempts to apply RST in the analysis of dialogue (cf. Fawcett and Davies, 1992; Maier and Sitter, 1992; Daradoumis, 1995). Martin (1992) criticized RST from this perspective, arguing that the deep structural embeddings that RST requires do not align well with the kind of clause combining observable in spontaneous speech. This continues to be an active area of debate.

Definitions

We gave an informal indication of the structure of an RST analysis above. We need to refine this somewhat for a full definition of RST. First, there are two kinds of rhetorical relations: asymmetric relations, where one of the related rhetorical units is singled out as the rhetorical head, or nucleus, and symmetric relations, also termed multinuclear, where all of the related units are of equal status. Examples of multinuclear relations are Contrast, which draws a relation between two elements – we cannot say that one of these elements is then more important than the other, it is precisely the function of the contrast to present them both – and Sequence, which orders an arbitrary number of elements in a temporal or other organizational sequence – again, we cannot pick one of these out as being more essential than the others.

In **Figure 1**, the symmetric relation of Sequence is shown. In this relation, the nuclei have identical status. The notation is standard in RST analysis, showing each relevant text span surmounted by a line showing its extent. The straight lines emerging from the text spans show that each span is analyzed as a nucleus.

The relation in **Figure 2**, which shows an example of a relation called Enablement, is an asymmetric relationship. The nucleus is still indicated by a straight line – vertical now – while satellites and their link with the nucleus to which they relate are shown by an arc.

The importance of a nuclear element is defined in terms of its contribution to the rhetorical goals of the text as a whole. Within RST, these goals are intended to correspond with the intentions of the speaker. A nuclear element cannot be removed from a text without damaging its coherence, whereas satellites can often be removed without compromising overall coherence (i.e., the text would still be perceived as attempting to fulfill the same broad communicative function).

The rhetorical relations themselves are defined in terms of applicability conditions; these are the rules that make up each relation and form a valuable guide

Figure 1 Symmetric relation: sequence.

Figure 2 Asymmetric relation: enablement.

to the analyst in explaining what is meant by each relation and how to select which one to use in a given context. Each relation defines:

- a set of conditions that must hold of the nucleus
- a set that must hold of the satellites
- a set of imputed conditions that must hold of the nucleus and satellite combination
- a specification of the effect that is achieved with the rhetorical relation on the hearer/reader.

The conditions are usually expressed in terms of the beliefs, intentions, and desires of the speakers and hearers. RST also considers the effect intended by the speaker/writer in using a relation.

For a good example of a relation definition, we can revisit the RST relation of Enablement. An example of a minimal text fragment involving Enablement can be seen in the sentence:

(3) Open the doors by pressing the red button.

In (3), the reader is told to do something, but is also told (in the 'by' phrase) how to do it. This is an example of Enablement, which relates the action to be performed to some subsidiary information that enables it (i.e., that makes the performance of the action easier or possible). It would also have been possible to present the information in two wholly separate clauses – 'Open the doors – press the red button.' for example. The relation definition is made up of four slots, as follows:

- Conditions on the nucleus (N): N identifies some action that it is possible for the reader/hearer (H) to

perform and which is, at the point in time at which the relation is given, ‘unrealized.’

- Conditions on the satellites (S): S identifies some information that improves the H’s ability to carry out the action identified in N.
- Conditions on the N+S combination: H comprehending S increases H’s potential ability to perform the action in N.
- The effect of the relation: H’s potential ability to perform the action in N increases.

Rhetorically, then, Enablement sees the action to be performed as the nucleus and the subsidiary information as satellites. We can see this with the current example by leaving out the enabling information ‘by pressing the red button.’ The main purpose of the text fragment appears to be that the hearer open the doors; this remains even when the enabling information is omitted. A generally useful way of viewing the nucleus–satellite relationship is therefore to say that the satellites increase the range of situations where the rhetorical force covered by the nucleus will be successful. In the current example, if the hearer knows how to open the doors anyway, then the enabling information may be safely omitted. But in situations where the hearer does not know this, the rhetorical force will fail without the satellites being present.

All of the rhetorical relations employed within RST are defined in this manner. A full list can be found in the definitive report of Mann and Thompson (1988), extracts from which, including the full relation definitions, are given on the RST website (see references). An almost exhaustive survey of the current state of the art in RST, the applications that are being pursued, references to RST analyses for a broad range of languages, as well as discussions of problems and issues, is available in two papers by Taboada and Mann (2005, 2006).

An analyst approaches a text through applying the relation definitions progressively, decomposing the text into ever-finer segments. Which relation to choose is determined by a good understanding of the applicability conditions (the information in the four slots seen above in the Enablement relation). Importantly, the applicability conditions must respect which discourse segments have been selected as nuclear and which as satellites. Sometimes it is possible to find situations where the conditions hold, but the nuclearity assignment would be wrong; this is sufficient to rule out the applicability of the relation considered. Moreover, when combining an RST fragment into a larger structure, it is the effect of the N+S combination that must be taken into consideration as a possible nucleus or satellite for the next level ‘up.’

In this way, the combination of structures into larger hierarchical structures is made to enforce a rhetorical consistency of purpose for a text as a whole.

The smallest piece of text that can participate in rhetorical relationships, the text span that is the finest level of rhetorical structure, is left open for the analyst to decide. Mann and Thompson deliberately allow this to vary depending on the purposes for which an analysis is undertaken. It may be fixed as sentences, as grammatical clauses, or as entire paragraphs, just as, in grammatical analysis, the analyst can decide how fine he or she needs the analysis to be. For English, a typical analytic decision is that the relations should apply to grammatical clauses but not within clauses. This may not be appropriate for all languages, however, because what may well be a grammatical clause in English could be a smaller grammatical unit in another language. Examples discussed here from the text type of instructions include the following contrasting pair from English and German:

(4a) Twist the top until it locks.

(4b) Drehen Sie den Deckel bis zum Anschlag.

What in the English version appears as a grammatical dependent clause (‘until it locks’) is in the German version a prepositional phrase (‘bis zum Anschlag’). Therefore, either the text spans for the rhetorical analysis must include at least prepositional phrases for German or the two corresponding sentences must receive differing rhetorical analyses – which may be unsatisfactory, given their very similar purpose. The exact positions taken on this issue in the literature vary; an extensive discussion was given by Grote (2004).

There are still many questions concerning how a body of rhetorical relations such as those proposed in RST are to be best identified, defined, and represented. Since the original collection of relations was presented as a simple set, many subsequent researchers concerned themselves with the question of just how large this set might need to become – in one collection, Maier and Hovy (1993) presented over 300 ‘rhetorical relations’ in a classification hierarchy. Moving in the other direction, Sanders *et al.* (1992) focused attention on four contrasting features for describing coherence relations and investigated these in terms of their psychological effects. Combining features then gives rise to particular rhetorical relations. One of these features, which they termed the basic rhetorical relation, concerns causality (i.e., whether two consecutive discourse segments are related in the world by causality or not). Here, Sanders *et al.* were able to demonstrate clear psychological effects that differentiate reliably between several distinct classes of relations. Reliability varied, however, across

the features considered, and so further work has subsequently investigated these issues more closely.

RST has been criticized because it only allows one rhetorical relation to hold between discourse segments. Some authors, e.g., Moore and Pollack (1992) and later Maier and Webber and colleagues (Maier, 1996; Webber *et al.*, 1999), argued that this particular RST constraint needs to be relaxed. Moore and Pollack suggested a solution by distinguishing between two main types of relations among those posited by Mann and Thompson – subject-matter and presentational relations. Subject-matter relations are those that take their applicability conditions from the states of affairs being described; presentational relations are dependent on the particular rhetorical argument being pursued by the writer/speaker. Moore and Pollack suggest that these two different types of relation should be allowed to hold at the same time.

In a move in some ways similar to the use of features by Sanders *et al.* mentioned above, Bateman and Rondhuis (1997) argued that rhetorical relations are not atomistic theoretical constructs at all, but bundles of features. They proposed that these features can be drawn from the three kinds of meanings commonly proposed in systemic-functional linguistics (see, e.g., Halliday and Matthiessen, 2004), thereby adding ‘textual’ meaning (concerned with nuclearity choices) to the ‘ideational’ (subject-matter) and ‘interpersonal’ (presentational) meanings already suggested by Mann and Thompson’s original account. This solves the multiple simultaneous relations problem by moving simultaneity to the features that hold rather than needing to maintain individual and separate rhetorical relations in the rhetorical structure.

An Example of RST Analysis

In this section, we give a very short worked example of text analysis according to RST. We take a simple recipe as indicative of the kind of analytic decisions and rhetorical relationships employed. The recipe is as follows:

Potted Cheese

Beat 225 g mature cheddar cheese and 50 g salted butter with 1 tsp dry mustard so that it forms a stiff cream. Spoon into small ramekin dishes. Cover with 50 g melted butter and refrigerate for 2 hours. When the potted cheese has set, serve spread on brown toast or crackers.

As many recipes do, this recipe consists of a set of sequential steps. These are represented in RST as a Sequence relation. However, there are two steps that are slightly more complex than the others. In the first,

a beating action is carried out *so that it forms a stiff cream*. This clause tells the reader why the beating is done, and is recognized in RST as a Purpose relation. In the second, the instruction is to *serve only when the potted cheese has set*. Because the *when* clause places a condition on when the action can be done, RST recognizes this as a Condition relation. So as well as taking part in the Sequence relation, these elements are themselves complex. The diagram in Figure 3 shows the full RST analysis of the recipe text.

Relations to Other Levels of Linguistic Description

RST is intended to cover the domain of linguistic description to do with ‘text structure.’ However, it is also necessary that this domain be related to other areas of linguistic description. One systematic problem haunting text linguistic accounts of many kinds has been that it is difficult to draw conclusions about what a particular text structure says about possible or impossible grammatical, lexical, and semantic expressions. This also has repercussions for the reliability of a text analysis; if it is not possible to state the observable linguistic signs of a text structural analysis, then it is possible to suggest several plausible analyses and hard to decide between them. RST does not position itself on this issue particularly clearly. While it is possible to posit a rhetorical relationship between elements without any supporting linguistic marker such as a discourse connective, it is much clearer positive evidence for a relation if an explicit marker is present.

In some cases at least, enough explicit evidence can be gleaned from texts to allow an RST analysis to be produced automatically. Marcu (2000a) followed this approach in considerable detail. Speakers also give explicit intonational signals that correspond to quite subtle distinctions in the rhetorical structure – in particular to structural embedding and nuclearity (see den Ouden, 2004). Nevertheless, it seems unlikely that fully automatic RST text analysis can ever be infallible. RST analysis explicitly draws on judgments of intention and belief, and reasoning about these is notoriously difficult to do automatically.

There are also situations where an RST analysis overlaps with analyses at other levels of linguistic description. For example, whenever an RST analysis is suggested for combinations of clauses, the relationships involved might also be described purely on the basis of grammar. For example, what, in RST terms, might be considered a Purpose relationship between a rhetorical nucleus and a satellite might, in terms of grammar, be seen as a purposive adverbial clause. There is probably little sense in asking which of

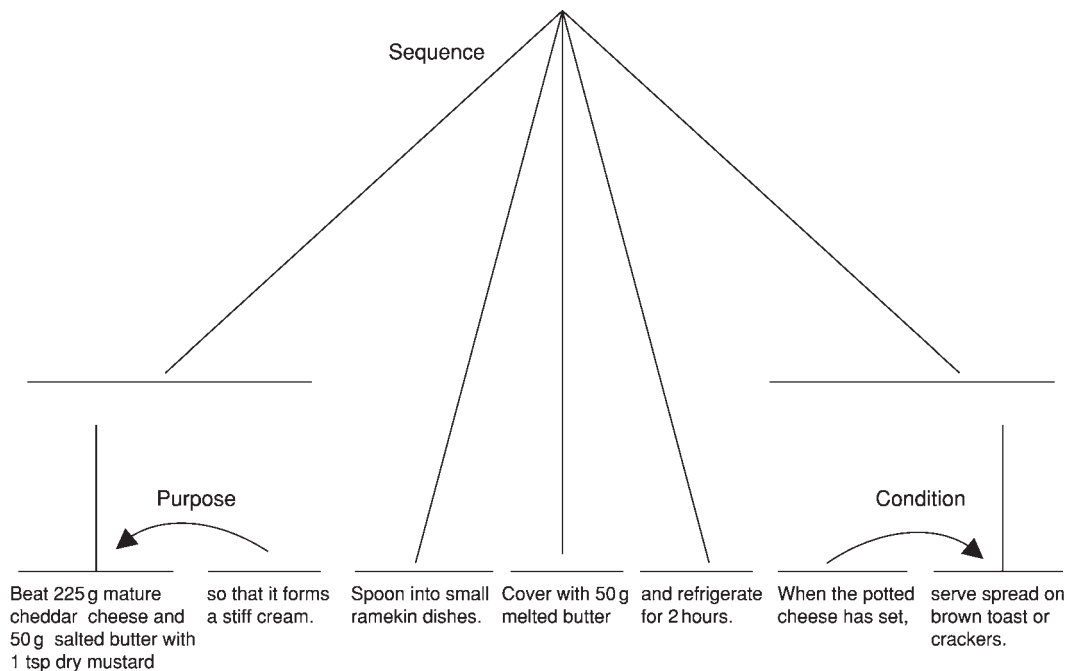

Figure 3 RST analysis of recipe for potted cheese.

these analyses is the ‘correct’ one; it simply depends what the analysis is trying to achieve. The fact that structural signaling can take place at either level has been studied in detail for clause combining by Matthiessen and Thompson (1989). The relationship with lower levels of grammatical structure may also be considered: Martin (1992) looked at how conjunctive semantic relations find linguistic realizations inside clauses and even within nominal and prepositional phrases, while Bateman and Rondhuis (1997) looked at the relationships between differing levels of abstraction in rhetorical organization in general.

Sometimes when an RST analysis is possible, it still seems less than useful to do so. An example offered by Mann and Thompson is that of analyzing a letter. There are segments of the letter, such as the address of the addressee, that of the sender, the date, the place where it was written, the salutation (‘Dear Ms Smith’), the sign-off (‘Yours in haste’), etc., which are normally part of letters but whose rhetorical linkage is weak. One could provide a rhetorical analysis, but for the most part it seems more appropriate to describe the textual structure involved as a generic structure for this particular text type. As such, it is similar to a partly frozen idiom that allows only limited innovation; the original rhetorical motivations (if any) of the organization have been lost, and one is left with a generic template of how instances of such text types are constructed.

The benefits of RST analysis obviously diminish progressively as one moves away from the central area for which RST is intended to operate. Carrying out analysis in terms of RST and other levels of description may, however, be useful when we are considering aspects of linguistic change, of the emergence of new grammatical configurations or generic text structures. Here, the kind of motivations that we obtain from the rhetorical level of description can indeed be useful indicators of reasons for change.

Applications of RST

As explained above, the first application of RST was in computational linguistics. Mann had been searching for an account of text structure that would be amenable to computational formalization, and with RST he succeeded. Two approaches to automatic text generation using RST were developed independently at the Information Sciences Institute; one by Hovy (1988) was essentially bottom-up, in that a collection of data was ‘structured’ in order to produce a well-formed RST tree; the other, developed by Moore and Paris (1988), interpreted the applicability constraints in the RST relation definitions as plan operators, i.e., methods for achieving goals that could be performed using the top-down hierarchical planning paradigm well-established in Artificial Intelligence (AI; see Sacerdoti, 1973). A detailed description of these uses of RST was given by Hovy

(1993), while computational introductions were given, for example, by Bateman and Zock (2003) and Vander Linden (2000). Essentially, production of a text starts with a communicative goal to be achieved, and the planning process successively refines this goal according to a library of plans into 'smaller' goals until an appropriate granularity for expression through rhetorical relations and unitary propositions is reached. The result is then a completed RST tree with constraints attached to all the leaves concerning the content and form of the linguistic material that is to be generated there, resulting in a specification for a well-formed text that realizes all the rhetorical goals. The approach was subsequently adopted in several large-scale natural language generation projects and for several languages (see, e.g., Rösner and Stede, 1992; Delin *et al.*, 1994); multilingual results have also fed into new accounts of contrastive pragmatics (Delin *et al.*, 1996).

RST subsequently became the approach to text planning most widely adopted in automatic text production but was not considered for text interpretation due to the perceived subjectivity – and therefore unreliability – of RST analyses. This changed substantially with the work of Marcu and colleagues (Marcu, 2000a; Marcu *et al.*, 2000), which sought to produce RST analyses of text automatically, drawing on a broad basis of surface linguistic cues. This could then be used for summarization of texts in the manner suggested by O'Donnell (1997), where successively removing deeply embedded satellites naturally results in shorter texts without impairing text coherence. Marcu (2000b) provides a book-length discussion of the issues and methods of RST-based automatic summarization and some of the problems of the approach.

A further development arising out of the use of RST for automatic text production was the extension to consider the creation of multimodal documents. The underlying intuition here is that, just as segments of a text contribute to that text's coherence in systematic and specifiable ways, segments of a multimodal document, involving pictures, diagrams, and texts, could also be related in an analogous manner. Such an extended RST approach involving relationships between text, diagrams, and pictures was set out by André and Rist (1993). This basic approach was subsequently adopted by a number of researchers and also used for computational implementations of document production systems. Perhaps surprisingly, little of the original RST specification needed to be changed in these efforts, although some more recent and detailed investigations of the differences between RST for texts and RST for multimodal documents have modified this view somewhat. Bateman *et al.*

(2004) showed, for example, that it is necessary both to extend the kinds of relations that are involved when we are relating parts of a document that are realized in different 'modes' and to consider the influence of the (at least) two-dimensional representational medium (e.g., the page or screen) rather than the one-dimensional medium of language assumed by RST (see also Henschel, 2002). Applications for the analysis and critique of multimodal documents, particularly of page layout and design, are one result of such studies (Delin and Bateman, 2002).

A further, recent proposal for an application of RST is for driving speech synthesis. In a series of detailed empirical studies, den Ouden (2004) shows that fine details of intonational delivery of texts read aloud correlate significantly with the RST analyses of those texts. These details include speed of delivery as well as intonational phrasing. It is then suggested that incorporating a responsiveness to the RST structure of a text would contribute to the naturalness of any synthesized speech for the text.

Finally, RST also continues to be influential both in linguistic approaches to investigations of text structure and in psycholinguistic attempts to validate or refine such approaches. Particularly important for the former are approaches that combine RST with aspects of information structure (Chiarcos and Stede, 2004; Taboada, 2004) and with interclausal coherence/cohesion when linearising a rhetorical structure in text (Bateman, 2001). For the latter, RST has offered a number of variables for more systematic investigation: nuclearity, structural embedding, and type of rhetorical relation are all clear claims of an RST analysis that can be subjected to empirical study. A range of investigations and theoretical discussion are presented by den Ouden (2004).

Compared with more traditional text linguistic approaches to describing and motivating text structure, RST can be distinguished by the detail given both to the methodology pursued when constructing an analysis and to the level of detail of the resulting analyses. The definitions of the individual rhetorical relations and the structural schemata in which they can be embedded significantly constrain analysis results. In studies carried out by den Ouden and colleagues (den Ouden *et al.*, 1998; den Ouden, 2004) it has been found that trained annotators reliably produced compatible RST analyses independently of one another; the rhetorical structures produced agreed most with respect to their segmentation and attribution of nuclearity, and less concerning the identity of individual relations. Detailed combinations of RST with other, more recent and formally specified linguistic approaches to text organization such

as Asher and Lascarides's Segmented Discourse Representation Theory (SDRT; Asher and Lascarides, 2003) or Discourse Tree Adjoining Grammars (e.g., Webber *et al.*, 1999) remain to be done but would no doubt be highly beneficial for subsequent research in text structure in general.

Rhetorical Tropes in Political Discourse

M Reisigl, University of Vienna, Vienna, Austria

© 2006 Elsevier Ltd. All rights reserved.

Classical Rhetorical and Actual Characterization of Tropes

The Greek substantive 'trópos,' originally meaning 'turn' or 'direction,' is derived from the verb 'trépein,' which signifies 'to turn (over/round).' The classical rhetorical term encompasses all figures of speech that involve a turn of meaning (i.e., a linguistic transference from one conceptual sphere to another). Conventionally, tropes are considered to be conventionalized means of expression of so-called 'improper speech' or 'nonliteral speech,' which is characterized by a (poetically) licensed difference between the

'ordinary' literal and the 'extraordinary' intended meaning of a speech. This tropological theory of deviation or substitution is nowadays often criticized for mistakenly assuming that tropes are deviations from linguistic normality and can thus simply be replaced by 'proper' expressions or phrases. However, tropes are, in fact, very common in 'everyday language,' and there is no such thing as an original *verbum proprium* or *substituendum* that perfectly corresponds to the trope (cf., among others, Kienpointner, 1999: 66–68).

In contrast to other figures of speech (e.g., figures of repetition like anaphora, epiphora, alliteration, assonance, consonance, and parallelism), tropes are said to be more closely related to content than to form or structure. Concerning the relationship between what is said or written and what is meant, Heinrich

Lausberg (1990a: 64–79) distinguishes between two types of tropes.

Tropes of shifting boundaries (*‘Grenzverschiebungstropen’*) consist of moving the borders of neighboring semantic fields or the borders within one and the same semantic field. These tropes are determined by a relationship of inclusion or (factual) contiguity between what is said or written and what is meant. They are, accordingly, divided into two subcategories. Periphrasis, litotes, hyperbole, emphasis, antonomasia, and synecdoche are assigned to the first subcategory. They are constituted by shifting the boundary within a semantic sphere. The second subcategory involves a relationship of adjacency. It is prototypically represented by metonymy.

The second type of tropes is labeled *‘leaping tropes’* (*‘Sprungtropen’*). In comparison to tropes that involve shifting boundaries, leaping tropes are grounded on a *‘leap’* from one semantic sphere to another sphere that is not adjacent to the first one. Traditionally, metaphor, allegory, and irony are taken as leaping tropes. Their intended meaning is to be found in a semantic domain that clearly differs from what is actually said or written. In concrete rhetorical analyses, a neat distinction between the two types of tropes – as well as between the single tropes allocated to these two types – is not always feasible, as simultaneous tropic membership of specific linguistic realizations is not unusual (see Fontanier, 1977; Morier, 1989; Lausberg, 1990a, 1990b; Groddeck, 1995; Plett, 2001, for various proposals to classify tropes; see Goossens, 1995, for multiple tropic membership, discussed with the example of *‘metaphtonymy,’* the simultaneous combination of metaphor and metonymy).

Antique rhetoric ascribes primarily an ornamental function to tropes. It considers them to be deviations from ordinary language for the sake of adornment. This view of tropes as purely decorative linguistic appendices that are *‘added’* to the linguistic raw material in the rhetorical production stage of elocution to give glamour to one’s speech has widely been overcome by a reassessment that sees language as basically tropic. Nowadays, it is almost commonplace in modern rhetoric, linguistics, language philosophy, and cognitive science that all areas of language are pervaded with tropes, and that tropes, like metaphors, metonymies, and synecdoches, function as elementary cognitive principles that – often unconsciously – shape and structure human perception and thinking. Tropes are no longer exclusively associated with the stage of elocution; rather, they are also related to the stage of *inventio* and, of course, to processes of the speech’s reception or apperception.

Political Discourses

The contention of the tropes’ pervasiveness in language holds also for the realm of political language, which – generally speaking – evolves in a tension between the preservation and transformation of power relations, public decision making, and problem solving, as well as political order. Many names of political institutions and *‘collective’* political actors have their origin in metaphorization and metonymization (e.g., *‘government,’ ‘parliament,’ ‘minister,’* and *‘ministry’*). Political discourses are full of tropes related to the three political dimensions of form (i.e., polity, the basic order related to political norms, institutions, system, and culture), content (i.e., policy, the policy-field-related planning and acting concerning the identification of political problems, the development and implementation of political programs, and the evaluation and correction of their implementation), and process (i.e., politics, the political competition related to the conflicts between political actors and to the achievement of followers and power). In all fields of political action – within and across which discourses manifest themselves – politicians employ these figures of speech as effective rhetorical means of constructing, representing, and transforming political *‘reality,’* as well as a means of political persuasion.

‘Fields of action’ (cf. Girth, 1996) may be understood as *“places of social forms of practice”* (Bourdieu, 1991: 74) or, in other words, as frameworks of social interaction (Reisigl, 2003: 148). The spatiometaphorical distinction among different fields of action can be understood as a differentiation between various functions or socially institutionalized aims of discursive practices. Among the political fields are the law-making procedure; the formation of public attitudes, opinions, and will; the party-internal formation of attitudes, opinions, and will; the interparty formation of attitudes, opinions, and will; the organization of international and (especially) interstate relations; political advertising; the political executive and administration; and the various forms of political control (for more details, see Reisigl, 2003: 128–142). A political *‘discourse’* about a specific topic may have its starting point within one field of action and proceed onward through another one. In this respect, discourses and discourse topics *‘spread’* to different fields and discourses. They cross between fields, overlap, refer to each other, or are in some other way sociofunctionally linked with each other (Reisigl & Wodak, 2001: 36 f.).

In the given context, *‘discourse’* is to be seen as topic-related concept that, among others, involves argumentation about validity claims such as truth

and normative validity, as well as pluri-perspectivity constituted by the discursive participation of various social actors who assume different points of view (Reisigl, 2003: 92; for a mono-perspectivist conceptualization of 'discourse,' see Fairclough, 1995: 14). Discourses represent semiotic social practices that are both socially constitutive and socially constituted. A political discourse about a particular topic can be understood as a complex bundle of simultaneous and sequential interrelated linguistic acts. These manifest themselves within, and across, the above-mentioned fields of political action as thematically interrelated and problem-centered semiotic (e.g., oral or written) tokens, very often as 'texts' that belong to specific semiotic types (i.e., textual types or genres), which serve particular political purposes (see Reisigl & Wodak, 2001: 36).

Rhetorical tropes fulfill many different purposes in political discourses, especially in regard to positive political self-presentation and negative political other-presentation. With respect to the ideational metafunction of language, these tropes help to 'invent' or construct a political 'reality' (e.g., via incorporating metaphors or allegories like the boat or ship metaphor/allegory, referring to a state), to reduce complexities by simplistic categorization and imaginary representation of political 'reality' (e.g., via color metaphors referring to alleged human 'races'), to vivify, personify, and illustrate abstract or unclear political ideas (e.g., via personifications and other animalizing metaphors), to selectively foreground specific traits of political entities or 'reality' sectors (e.g., via particularizing synecdoches), and to background or hide specific political aspects, actors, or actions (e.g., via metonymies that represent persons by place names).

With respect to the interpersonal metafunction of language, these tropes are employed to promote the identification with single or 'collective' political actors (e.g., leaders, parties, states, or nations), as well as with their political aims and ideologies (e.g., via the heart metaphor relating to a specific nation-state within a confederation of states); to promote in-group solidarity (e.g., via family or kinship metaphors, such as the androcentric metaphor of brotherhood), referring to the imagined community of a nation or of politically united nations; to support out-group segregation and discrimination (e.g., via deprecating animalizing metaphors like parasite, rat, and vermin); to create a feeling of security by suggesting stability and order (e.g., via construction metaphors like house, referring to a state); to create a feeling of insecurity by suggesting chaos, disorder, danger, and threat (e.g., via flood or wave metaphors

referring to immigrants); to justify, legitimize, or delegitimize specific political actions or their omission (e.g., via metaphors of gain or cost relating to the consequences of a specific action or omission of action); and to mobilize political followers to perform specific actions which can culminate in physical or military aggression, such as war (e.g., via instigating militarizing metaphors or rape and monster metaphors relating to 'the enemy'). Some of these functions will be elaborated on in greater detail in the following section.

Toward a Tropology of the Political

For a long time, analysis of political language has merely been carried out as a side job both on the part of political scientists interested in issues of language and on the part of linguists interested in political issues. As a consequence, the respective studies in linguistics and political science have frequently been amateurish with respect to theory, methods, and methodology. This critique also relates to the study of tropes in political discourses. Linguistic, and especially rhetorical, approaches often have suffered from politological ignorance and did not venture beyond a positivist identification and enumeration of figures of speech, as well as a very general characterization of the persuasive or manipulative potential of single tropes, especially of metaphors. The analyses of tropes in political science did, however, often not exceed everyday linguistic triviality when selectively looking at 'linguistic images' with political significance.

A remedy for the many shortcomings in the area can be found in a transdisciplinary politolinguistic approach that tries to connect and synthesize rhetoric, linguistic discourse analysis, and political science. Such an approach should theoretically rely on actual concepts in political science, as well as on rhetorical and discourse analytical categories. With respect to the topic in question, politolinguistics should build a 'tropology of the political' (i.e., a theory of tropes that systematizes and explains the political and linguistic functions or purposes of tropic language in polity, policy, and politics; for a first sketch, see Reisigl, 2002, and Reisigl, 2003: 237–258). In what follows, this tropology is outlined with the example of three of the four so-called 'master tropes' (see Burke, 1969: 503–517); that is to say, with the example of metaphor (including personification and allegory, the latter being conceived as continuous, expanded metaphor), metonymy, and synecdoche (including antonomasia as a special form of synecdoche). The fourth alleged 'master trope,' irony, will be dropped,

as its character is very different from that of the three basic tropes. In contrast to metaphor, metonymy, and synecdoche, irony is much more heterogeneous. It often involves the prosodic, gestural, or facial-expressive dimension of language, which enables one to recognize that what has been said is not to be taken literally, but ironically. To explicate the complex character of irony would go beyond the scope of this introductory article.

In addition, in the present context, for reasons of limited space, no attention can be paid to other linguistic occurrences traditionally also apostrophized as ‘tropes.’ Periphrasis, litotes, hyperbole, and emphasis are – as is irony – much more heterogeneous than metaphor, metonymy, and synecdoche. As rhetorical phenomena, they do often derive from the three basic tropes or manifest themselves in manifold tropic ways. Periphrasis, for instance, can linguistically be realized as *antonomasia* (which is characterized as a descriptive phrase standing for an individual to be identified with a proper name or, conversely, as a proper name standing for a general character trait), *synecdoche*, *etymology* (which is based on the principle of ‘*nomen est omen*’), *metaphor*, *allegory*, *metonymy*, *euphemism*, *descriptio* and *definitio*, and so forth (Plett, 2001: 91). However, some of these other ‘tropes’ frequently involve linguistic dimensions that are not genuinely related to tropes, such as the so-called ‘trope of emphasis,’ for example, which comprises numerous phonological, morphosemantic, and syntactic characteristics that are not to be seen as tropic qualities (Reisigl, 1999: 197–199). To take into consideration all these various aspects and their complex interplay would not be feasible within the limits of this overview.

Metaphors

Of all tropes, metaphors certainly receive the most attention in the analysis of political discourses. Many studies have been carried out in the last decades that focus on metaphorical speech in different political and historical contexts (cf., among many others, Lakoff, 1991, 1992; Chilton & Ilyin, 1993; Chilton & Lakoff, 1995; Schäffner, 1995, 2002; Chilton, 1996; Semino & Masci, 1996; Böke, 1997, 2002; Musolff, 2000; El Refaie, 2001; Klein, 2002; Panagl & Stürmer, 2002; Stürmer, 2002).

Theoretically, metaphors can be understood as ‘impertinent predications’ (Ricœur, 1986), in the sense that an expression is semantically incompatible with the context of meaning in which the expression is uttered. Metaphor establishes a similarity between two different semantic domains. As it “is a device for

seeing something *in terms of* something else” (Burke, 1969: 503), it is most closely connected with the question of perspectivation.

Many different types of metaphor occur in political discourses. Some metaphors transform inanimate ‘objects’ into animate ones, whereas others transform animate ‘objects’ into inanimate ones. Some metaphors predicate onto animate ‘objects’ the quality of other animate ‘objects,’ whereas others predicate onto inanimate ‘objects’ the quality of other inanimate ‘objects.’ Some transform abstract entities into concrete ones that are sensually perceivable, and others merge different human senses synesthetically or into *catachresis* (cf. Plett, 2001: 101–104). Many metaphors in political discourses transfer aspects from the economic to the political domain, and many from the domain of private life and family life onto public life and ‘collective actors.’ Various metaphors project elements from the domains of sports onto the political domain. All these and many other metaphorical types (including those that will be mentioned in the following explications, which for the most part are also to be found in Reisigl & Wodak [2001: 58–60]), should be taken into consideration by an elaborated phenomenology of metaphors in political discourses.

Personifications or anthropomorphizations are metaphors that bring together and link two different semantic fields, one with the semantic feature (–human), the other bearing the semantic feature (+human) (cf. Lakoff & Johnson, 1980: 34). Personifications are rhetorically used to give a human form, to humanize inanimate objects, abstract entities, phenomena, and ideas. They play an important role in animating imagined ‘collective subjects’ – as, for example, ‘races,’ ‘nations,’ ‘ethnicities,’ ‘states,’ ‘state unions,’ and many other political ‘collective’ actors (cf. Goodwin [1990] for the question of ‘engendered’ nations). Their apparent concreteness and vividness often invites hearers or readers to identify or to feel solidarity with or against the personified political entity.

In addition to personifications, there are many other forms of metaphors that are important in referentially and predicationally constructing in-groups and out-groups in politics and polity, whether they are imagined as ‘races,’ ‘nations,’ ‘ethnicities,’ ‘states,’ and ‘tribes’ or as specific ‘racialized,’ ‘national,’ ‘ethnic,’ or ‘religious’ majorities or minorities. Many of these metaphors function as ‘collective symbols.’ Very often, they are simultaneously used both as metaphors and representative *synecdoches* (cf. Gerhard & Link, 1991: 18).

In discourses about ‘races,’ ‘nations,’ and ‘ethnicities,’ these metaphors and *synecdoches*, but also the

respective metonymies, are almost always connected with specific dichotomic, oppositional predications that can form networks of semantic isotopes that help politicians to polarize and divide the world of social actors into 'black and white' and into 'good and bad.' The most frequent and conspicuous of these predications to 'real' or imagined social actors and political systems that serve positive self-presentation and negative other-presentation are those of singularity/uniqueness/distinctiveness or individuality, of identity or similarity, of collectivity, of difference, of autonomy/independence, of heteronomy/dependency, of continuity, of discontinuity, of (social) inclusion, of integration, of union or unity, of (social) cohesion, of (social) exclusion, of fragmentarization, of multiplicity, and of dissolution.

Apart from these rather abstract identity-related attributions realized by metaphors, 'national,' 'racial,' and 'ethnic' stereotypes or 'characters' are predicated on the basis of metaphors, relying on the collective symbolic concepts of materiality and body; of material status (e.g., the thermostat settings of 'warm' versus 'cold') and states of matter (solid, fluid, and gaseous); of material qualities like weight ('heavy' versus 'light'); of spatiality, spatiodynamics, and temporality ('fast,' 'fast-moving,' 'ephemeral,' 'persistent,' 'tenacious,' 'lively,' 'mobile,' 'flexible,' 'slowly,' 'inert,' and 'lethargic'); and of the five sensorial concepts of visibility ('fair,' 'pale,' 'clear,' and 'transparent' versus 'dark,' 'gloomy' 'obscure'), audibility ('harmonious' versus 'loud' and 'noisy'), tactile sensation ('hard' versus 'soft'), olfactority ('nice-smelling' versus 'stinking'), and taste ('tasteful' versus 'tasteless').

Racializing, nationalizing, and ethnicizing metaphors of spatiality are primarily ordered around the symbolically and evaluatively loaded binary oppositions of 'internal' versus 'external' or 'internality' versus 'externality,' of 'height/top' and 'up' versus 'bottom' and 'down/low,' of 'foundations/profundity/ground' versus 'bottomlessness,' of 'superficiality' and 'flatness' versus 'depth,' of 'center' versus 'periphery/margin,' and of 'boundary,' 'limit,' and 'extension/expansion' and 'spreading' (see Mayr & Reisigl, 1998).

Metaphors of 'racial,' 'national,' and 'ethnic bodies' and 'materiality' are often also derived from naturalizations; that is, from meteorologizations, geologizations, and biologizations. To the latter belong, in addition to the personifications already mentioned (both nongendered and gendered), animalizations (of both sexes) and florizations.

Taking the example of German and Austrian discourses about migrants and 'racialized,' 'national,' and 'ethnic' minorities, the most frequent and stereotypical metaphors employed in the negative

construction or identification of social actors and in the negative predication of them, of their migration, and of the alleged effects of immigration are the following (see Böke, 1997, 2002; Gehard & Link, 1991): *natural disasters*: immigration/migrants as avalanches or flood disasters; *dragging/hauling*: illegal immigration as dragging or hauling; *water*: immigration/migrants as a water-course/current/flood that has to be 'dammed'; *fire*: alleged effects of immigration/conflicts between 'racialized,' 'nationalized,' or 'ethnicized' groups' as a smoldering fire; *thermostatics*: effects of immigration as pressure within the pot and conflicts between 'racialized,' 'nationalized,' or 'ethnicized' groups' as bubbling; *plants and fertile soil*: migration and effects of migration as transplantation/repotting, uprooting, (alleged) causing of social conflicts as seeding; *genetic material*: cultural and social traditions and 'heritage' as genetic material; *growth/growing*: increasing immigration and increasing conflicts as growing; *pollution and impurity*: intergroup contacts, exchanges, and relations as pollution and impurity; *melting*: intergroup contacts, relations, exchanges, and assimilation as melting; *body*: 'racialized,' 'nationalized,' 'ethnicized' groups are metaphorically ascribed 'collective (racial, national, ethnicity) bodies,' outgroups are metaphorized as 'foreign bodies' or alien elements; *blood*: immigration as bleeding white or bloodletting of the imagined 'collective bodies,' intergroup relations as blood impurity; *disease/infection*: immigration/migrants as an epidemic, intergroup contacts and relations as an infection; *animals/animal-owning*: immigrants/minorities as parasites, as 'attracted like the moths to a flame,' as herded together; *war/fight/military*: immigration as military activity/invasion; *goods/commodities and exchange of goods*: migration as import and export of workers/workforce, migrants as 'freight'; *food*: 'good/welcome immigrants/minorities' versus 'bad/unwelcome immigrants/minorities' metaphorized as the wheat that has to be separated from the chaff; *vehicle/boat/ship*: effects of immigration as overcrowded boat; and *house/building/door/gateway/bolt*: the ingroups' (e.g., 'national') territory as house or building, and stopping immigration as bolting the door. All of these metaphors are employed in discourses about migrants and migration as implicit argumentation schemes (i.e., as implicit and often fallacious conclusion rules that serve to legitimise discrimination; cf. Pielenz, 1993). The persuasive function of these metaphors may be exemplified with the metaphors of avalanches and flood. The two metaphors suggest that 'If something (e.g., immigrants) is an avalanche or flood, it should be avoided or prevented.' The implicit argumentation function

of all the above-mentioned conceptual metaphors is explicable by corresponding if-then schemes.

The suggestive force of metaphors can be so strong as to motivate metaphorologists like Lakoff to contend that 'metaphors can kill' (Lakoff, 1991). In view of animalizing metaphors such as 'rat,' 'parasite,' and 'vermin,' referring to Jews during the National Socialist dictatorship, and implying that if somebody is a harmful vermin, rat, or parasite, he or she should be exterminated, such a metonymical assertion does not appear to be an exaggeration.

The tension between the preservation and transformation of political order, problem-solving, and power relations becomes clearly manifest in the area of metaphorical language. Just to offer a few hints: static metaphors, metaphors of incorporation as well as space and container metaphors seem to be favored if questions of polity, policy, and politics are a matter of consolidation and preservation, whereas destructive and (re)building metaphors, as well as dynamic metaphors (e.g., metaphors of movement and journey), indicate (intended) political transformation. Metaphors with negative connotations implying standstill are employed to evaluate preservation negatively (e.g., 'fossilization of political structures'). Metaphors with negative connotations implying political change are employed to evaluate transformation negatively (e.g., 'dismantling of political infrastructures').

Metonymies

Metonymies (from the Greek: 'renaming,' 'name change') are constituted by a shift involving two semantically (and materially, causally, or cognitively) adjacent fields of reference: a name of a referent stands for the name of another referent, which semantically (abstractly or concretely) adjoins the referent of the name (cf. Morier, 1989: 749–799; Lausberg, 1996: 292–295; Groddeck, 1995: 233–248; Plett, 2001: 98–100).

Depending on the relationship between the two neighboring conceptual fields, one can, among other things, distinguish between the following metonymies: (1) the name of a product or effect stands for the cause or author/creator ('The racist book [standing for its author] provoked many enraged reactions.');

(2) the name of a cause or author/creator stands for the product or effect ('The new Clinton [standing for the new book authored by Clinton] is a best-seller.');

(3) the name of an object stands for the user of the object ('The cars [standing for their drivers] pollute and endanger the environment more and more.');

(4) the name of a container stands for the container's content ('Bush used to drink several

glasses [standing for the alcoholic liquid the glasses were filled with] every day.');

(5) the name of a place (e.g., a state/country, town, city, district, or village) stands for the person or persons living at the place ('Italy is not willing to accept more refugees. '; 'Haider says what Austria thinks.');

(6) the name of a building stands for the person or persons staying, working, imprisoned, and so forth, there ('The White House decided to attack Iraq. '; 'The concentration camp Dachau was liberated in 1945 on May 2nd.');

(7) the name of a place stands for an action performed at the place or an event located at the place ('Auschwitz must never ever happen again.');

(8) the name of a person stands for the country or state in which the person is living ('Cooperation is important because we are too small to allow disharmony in vital areas of our country. ', as the former Austrian foreign minister, Wolfgang Schüssel, said on 15 May 1995, in his speech commemorating the fiftieth anniversary of the signing of the international 'Austrian State Treaty.');

(9) the name of a person or of a group of persons who have lived in the past stands for a person or a group of persons who are living in the present ('We already fought against Prussians' imperialism centuries ago.');

(10) the name of a time, time period, or epoch stands for the persons living in the time, time period, or epoch ('The twentieth century has seen the most extreme political developments in human history.');

(11) the name of an institution stands for (responsible) representatives of the institution ('The government proposes a more restrictive asylum act.');

(12) the name of an institution stands for actions performed within the institution or events that take place in the institution ('The Second Austrian Republic has almost always been described as a history of successes. '); and so on.

As one can see from examples 1, 3, 5, 6, 7, 10, 11, and 12, metonymies enable speakers and writers within all of three political dimensions to conjure away responsible, involved, or affected actors (whether victims or perpetrators) or to keep them in the semantic background. Example 9 illustrates how a nationalist identification with the past manifests itself by the usage of the 'historical we.' Example 2 realizes the strategy of metonymic personalization, which aims to stress the focus on a single politician. Example 8 illustrates the strategy of metonymic concretizing and personifying (please note the doubled tropic membership) that aims to promote political identification and solidarity. Example 4 finally shows a very conventional type of metonymy, which in the specific context, could also be read as euphemistic circumlocution of Bush's former alcoholism.

Metonymies of the type 'place name for persons' seem to be among the most frequent ones in political

discourses. They often realize the strategy of presupposing intragroup or intra-‘collective’ sameness or similarity (see Wodak *et al.*, 1999: 43). Such an assimilating or homogenizing function is, however, also fulfilled by synecdoches and specific metaphors.

Synecdoches

Synecdoches (from the Greek: ‘understanding one thing with another’) are turns of meaning within one and the same semantic field: a term is represented by another term, the extension of which is either semantically wider or semantically narrower (cf. Morier, 1989: 1159–1175; Lausberg, 1990b: 295–298; Zimmermann, 1989; Groddeck, 1995: 205–220; Plett, 2001: 92–94). According to the direction of representation, two types of synecdoches are distinguished (cf. Plett, 2001: 92–94).

The particularizing synecdoche is constituted by a representative relation that consists of a semantically broader concept standing for a semantically narrower concept. The three main subcategories of this type of synecdoches are *pars pro toto* (i.e., the part stands for the whole: ‘Hitler [representing Nazi Germany] was finally defeated.’), *singularis pro plurali* (i.e., the singular stands for the plural, forms a ‘collective singular’: ‘The Swiss are industrious.’), and *species pro genus* (i.e., the species stands for the genus: ‘The refugee doesn’t have a penny to her name [‘penny’ stands for ‘money’].’).

The generalizing synecdoche is established by a semantically broader concept that represents a semantically narrower one. The three principal subcategories of generalising synecdoches are *totum pro parte* (i.e., the whole stands for the part: ‘Denmark is world champion.’ [this synecdoche is also a metonymy]), *pluralis pro singulari* (i.e., the plural stands for the singular: ‘We [representing a single person like a queen or a state’s president; cf. *pluralis maiestatis* or *pluralis modestiae*] hereby enact a general amnesty.’), and *genus pro specie* (i.e., the genus stands for the species: ‘Mankind has not learnt anything from history.’).

In political discourses, the particularizing synecdoche, just like the generalizing synecdoche, is a means of referential annexation, assimilation, and inclusion. Particularizing synecdoches like the ‘foreigner,’ the ‘Jew,’ and the ‘American’ serve stereotypical generalization and essentialization, which refer in a leveling manner to a whole group of persons. In languages like German, Italian, and French, these are almost always realized in their masculine grammatical form.

Lakoff & Johnson (1980: 38) have introduced – as a special conceptual synecdoche – the synecdoche of

the ‘controller for controlled’ type –, in which leaders, people in power, rulers, and so on stand for the persons who are actually carrying out an action (e.g. ‘Bush bombarded Baghdad.’; see also the first synecdoche example). The use of this form of particularizing synecdoche is a central feature of all ‘monumentalist historiography’ (Nietzsche, 1985) that hides social actors behind their leaders if speakers and writers judge them to be historically insignificant. Even if one does not assume, as do Lakoff and Johnson (1980), that the synecdoche is a special form of metonymy, it seems equally plausible to allocate the type ‘controller for controlled’ to the category of metonymy.

The crucial role of synecdoches in polity, policy, and politics has not yet been recognized adequately, even though there are first attempts to grasp the political relevance of this trope (see, for instance, Palonen [1995], who analyses party names like ‘The Greens’ as synecdoches), and even though Kenneth Burke stated more than 35 years ago that every act of social representation and every theory of political representation involves the trope of synecdoche, if “some part of the social body (either traditionally established, or elected, or coming into authority by revolution) is held to be ‘representative’ of the society as a whole” (Burke, 1969: 508).

Burke’s observation may serve as a starting point for a general conceptualization of the relationship between synecdoche and political representation. Synecdochic representation is a basic political principle wherever more stands for less, or less stands for more. Several factors determine whether or in what way a political system of representation is organized democratically: Who is entitled to be a political representative, and who decides on the question of who will be a representative (active and passive right to vote)? What does the procedure of political authorization to be a representative look like (direct or indirect democracy)? Under which conditions and when can the relationship of representation be dissolved or confirmed (representation for a set time)? To what extent are representatives bound to those who are represented (free or imperative mandate)?

There are different levels of political representation, which can be differentiated when looking at political systems. On the highest level, there are to be found, according to the political system, emperors, kings and queens (monarchy), states’ presidents and chancellors (republic and democracy), or dictators (totalitarian dictatorship). Depending on the level of representation, one and the same politician is more or less representative. That is to say, at a lower level of integration, a politician (e.g., a party leader) may represent all members of a specific group

or political organization, whereas she or he just represents a minority at a higher level of the system (e.g., in the case that the party is a very small one). These dynamics become very complex in modern democracies, and all the above-mentioned determinants have to be taken into consideration by a tropological model of political representation (for more details, see Reisigl, 2003: 252–258).

Until now, an elaborated tropology of the political does not yet exist, although a developed politolinguistic theory of tropes that scientifically and fruitfully connects rhetoric, linguistic discourse analysis, and political science is an urgent desideratum. Only such a transdisciplinary approach is capable of systematizing and explaining the many different political and linguistic functions of tropic language in polity, policy, and politics in a differentiated way that does justice to the complex topic in question.

S

Sacks, Harvey

W Bublitz, Universität Augsburg, Augsburg, Germany

© 2006 Elsevier Ltd. All rights reserved.

Harvey Sacks graduated from Columbia College, New York in 1955 and earned his Bachelor of Law at Yale Law School in 1959 and his Ph.D. in sociology at the University of California, Berkeley in 1966. Aged 40, he died in an automobile accident in California, where he had taught at the University of California in both Los Angeles and Irvine since 1963. Sacks is best known for his invention of 'conversation analysis.' Even though he published relatively little in his lifetime, his ideas spread continually, chiefly through his numerous university lectures and conference papers; his influence expanded greatly when his lectures were published posthumously in 1992.

Most consequential for the development of his highly original accomplishments in sociology and linguistics was his contact with Harold Garfinkel (and his ideas on ethnomethodology) and Erving Goffman. The influence of Goffman's work in interaction analysis, i.e., the description of how participants behave in normal, everyday interactive encounters, is particularly evident in Sacks's early studies (on suicide help conversations), in which he began to move away from the established quantitative techniques and preanalytic methodology of mainstream American sociology. Instead, he adopted central concepts of ethnomethodology, which is chiefly concerned with the means and methods employed by interactants to create and act within their own social reality. Accordingly, he strongly argued against the widely shared belief that social norms, roles, and rules are statically and objectively given, prior to and independent of the interactants' verbal (and accompanying non-verbal) behavior, in which they are merely reflected. Being convinced that, on the contrary, social order is continuously achieved in social encounters by the participants' skillful use of language, he introduced 'conversation analysis' as an alternative (and by now major) approach. His aim was to prove that social norms are most adequately described not from a global but from a local point of view. The

analyst's task is to meticulously describe the minute details of as many instances of ordinary everyday conversational events (telephone conversations, newspaper stories, jokes) as possible in order to discover systematically recurrent patterns of methods and means that interactants use collaboratively and routinely to negotiate, i.e., establish, maintain, and vary, social order. Conversation analysis is thus an inductive and strictly empirical data- though not theory-driven approach. Preexisting theories with their descriptive categories and rules, which have been independently developed for unspecified sets of data, are rejected as being neither necessary nor applicable to the analysis of naturally occurring (recorded and transcribed) discourse. Instead, analysts develop the necessary descriptive categories while analyzing the data; categories arise in and out of the analytical process and are based on observation, not intuition.

Conceptual landmarks of Sacks's studies of the mechanisms of talk-in-interaction include turn-taking organization (how and where speaking turns occur, how speakers select others or are selected themselves as next speakers, how turns are structured, etc.), topic organization, opening and closing procedures, mechanisms of self-correction and repair, preferred ways of referring to other people and telling stories in conversation, and the sequential organization of conversation with 'adjacency pair' as its key concept. These are pairs of speech acts whose first part sets up a slot with a 'conditional relevance' for an expected, i.e., preferred, second part, thus constraining the interlocutor's choice; examples are question-answer, statement-agreement or – contradiction, invitation-acceptance or – decline, reproach-justification, and also greeting-greeting. It follows that each contribution to an ongoing conversation is both responsive and initiative. By simultaneously taking up the preceding and setting up expectations for the following turn, each interactant reveals his or her understanding of what is going on, what activities are currently performed, and what interactional frames are shared. In this way, participants continually display their awareness of how their use of language contributes

to the constitution of the social event they are engaged in. In his later work (from 1968 onward), Sacks broadened his perspective and preferred a more global to the earlier local, occasionally *ad hoc*, and detailed approach to conversational interaction; his work took “a turn toward systematicity and toward the relevance of substantial amounts of data” (Schegloff, 1992b: xi).

Summing up Sacks’s legacy, Schegloff lists four aspects: methodology (“of how to study human sociality”), topic (the “recognition...that talk can be examined in its own right, and not merely as a screen on which are projected other processes”), discipline, and inspiration (Schegloff, 1992a: xii ff.). However, even though the richness, originality, and intellectual vigor of his work together with his “ability to turn the apparently trivial into the gripping and insightful” (Silverman, 1998: x) are apparent from the available oeuvre, the significance of his beliefs is not generally recognized (Silverman, 1998). Not surprisingly, the methods of conversation analysis (being rigorously empirical, inductive, and interactant centered) have also been criticized as being too positivistic, operating in an interest-, ideology-, and culture-free vacuum.

Sapir, Edward

J G Fought, Pomona College, Claremont, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Edward Sapir was born in Lauenberg, Pomerania. His family immigrated to the United States in 1889. He received his higher education at Columbia University, earning his B.A. in 1904, an M.A. in Germanic languages the next year, and completing his Ph.D. in anthropology in 1909, along with some advanced studies in historical and comparative linguistics.

He was first exposed to Native American languages as a graduate student under the direction of Franz Boas. The new approach to anthropology developed (and largely administered) by Boas integrated the study of cultures and their languages, as both were manifested in the content and form of traditional texts. Few would dispute that Sapir was unequalled among American anthropologists of his generation. Between 1907 and 1910 he held research fellowships at the University of California and the University of Pennsylvania. From 1910 to 1925, he was in charge of the new Division of Anthropology of the

Geological Survey of Canada, based in Ottawa, enabling him to sponsor field studies by himself and others.

Sapir's intense, far-reaching field work began in 1905, with a Wasco-Wishram Chinookan, and over the next five years alone he covered six other languages, including his landmark description of Takelma (completed in 1911, and published in 1922) making him the paragon of Boasian, linguistically driven anthropology. Sapir's extraordinary energy and phonetic skills were the foundation for his capacity for quickly, accurately, and insightfully compiling and analyzing vast amounts of textual and grammatical data from a wide range of American languages. Unlike his contemporary Leonard Bloomfield, whose informant sessions were carefully nondirective, Sapir drew in and mobilized his informants, training them to write accurately in their own languages and to compile and translate traditional texts, which he then worked through with them. Early in their careers, the descriptive writings—the linguistics—of Sapir and Bloomfield seemed more alike in method than their later works. These apparent differences owe something to their very different personalities and their divergent rhetorical styles. It seems likely also that Sapir's wider anthropological responsibilities played a role. That each understood and respected the other's work can be seen in Sapir (1931) and Bloomfield (1922).

Sapir's training in historical and comparative linguistics prepared him to exploit the growing body of data from American languages as a means of dating cultural contacts and migrations through linguistic evidence. In his extremely important monograph on *Time perspective* (1916; reprinted in Mandelbaum, 1949) he recast the older Powell classification of language relationships produced by the Bureau of American Ethnology, which recognized 55 separate stocks. Sapir reduced these to six, in a bold reclassification that is still an active topic of discussion.

In 1925 Sapir accepted an appointment to the University of Chicago. The position opened up new interdisciplinary connections for him: there were linkages with distinguished colleagues in sociology, psychology, and political science. Sapir moved again, to Yale, in 1931. During this period, he worked extensively in culture and personality studies, a field he was instrumental in launching. One of his students at Yale was Benjamin Lee Whorf, whose name is linked with his in connection with a characteristically intuitive hypothesis concerning the mutual influence of habitual forms and patterns in language and culture.

Mandelbaum (1949) presented a selected cross-section of Sapir's important linguistic and anthropological publications. This collection prompted Zellig Harris (1951) to give Sapir's linguistics and its role in the development of the field a long, insightful review. Sapir's collected works, to appear in 16 large volumes, are even now only half published. Native American language texts, grammars, and related linguistic anthropology amount to more than half of this material, an imposing monument to his genius, his energy, and his mastery of the arts of phonetic transcription and morphological analysis. His skill in addressing the public can be enjoyed in his popular book *Language* (1921), which is still in print, still gives the clearest, most accessible picture of a linguist's work, and still attracts new readers to the field.

Scaffolding in Classroom Discourse

S M Bortoni-Ricardo, University of Brasilia,
Brasilia, Brazil

© 2006 Elsevier Ltd. All rights reserved.

The concept of scaffolding is grounded in the classroom discourse tradition and draws on two scholarly perspectives, developed in the realms of psychology and sociolinguistics, namely, the sociocultural theory of language and learning, as put forward by the Russian psychologist Lev S. Vygotskij, and the sociolinguistic approach to human interaction according to John Gumperz and others. These two strands of theory share a view of language as the foundation of learning and place emphasis on human actions as jointly constructed efforts.

Scaffolding is a metaphorical concept that refers to the visible or audible assistance that a more expert member of a culture can give to an apprentice.

Scaffold work is most often analyzed as an instructional strategy in the school domain, but it occurs in any social setting where socialization processes take place.

The term 'scaffolding' was introduced by the American psychologist Jerome Bruner (1983) whose main interest was in the institutional forms by which culture is passed on. A basic concept underlying his work is Vygotskij's zone of proximal development (ZPD). This zone lies in between what learners can do without assistance and the maximum they can do with the help of a more experienced partner (see Vygotskij, Lev Semenovich).

According to Vygotskij's sociohistorical theory, external speech affects internal thoughts: the intrapsychological apprehension of knowledge is made possible by the interpsychological action.

Another concept underlying the rationale of scaffolds is contextualization cues as advanced in Interactional Sociolinguistics, i.e., "any feature of linguistic form that contributes to signalling to the participants whether communication is proceeding smoothly and how intentionality is being communicated and interpreted" (Figueroa, 1994: 113). Contextualization cues are conveyed through multiple

linguistic and paralinguistic channels, such as prosodic features (pitch and tone, loudness, rhythm) and kinesics (facial decoration, eye gaze, smiles, frowns, and any other resources of the body idiom), which are important tools in the management of scaffold-like actions (see **Gestures, Pragmatic Aspects**). Hence the advantage of using a microethnographic methodology to segment any scaffolding episode into smaller interaction units.

In the tradition of classroom discourse, scaffolding is associated with teacher initiating and evaluating the students' responses within the IRE (initiation-response-evaluation) framework of classroom interaction. This can take the form of prefaces to questions, overlapping, backchanneling, comments, rephrasing, and expansion of pupils' answers that will provide them with an opportunity for reconceptualization (Cazden, 1988) (see **Classroom Talk**).

A basic feature of scaffolds is the establishment of a positive atmosphere between the participants whereby teachers support (scaffold) the students' enactment of a competent behavior. This can be done through ordinary actions that ratify the learner as a legitimate participant, such as listening to them, as the late Brazilian educator Paulo Freire has pointed out (Freire, 1997). The scaffolding assistance in the classroom can come from the teacher as well as from peers.

Scaffolding strategies are culture-specific and can vary largely across social networks, ethnic and cultural groups, and national communities.

Second and Foreign Language Learning and Teaching

P Skehan, The Chinese University of Hong Kong, Shatin, New Territories, Hong Kong, SAR, China

© 2006 Elsevier Ltd. All rights reserved.

Not that long after the execution of his brother, Vladimir Lenin was himself banished to Siberia because of his political activities. In Imperial Russia, Lenin knew that the sequence of punishments for political offenses was first imprisonment, then banishment to Siberia, then banishment abroad, and then, execution. He was on step 2 of this sequence. He also knew that after his period in Siberia he would not cease his political activities and that the next stage would very likely be banishment outside Russia. Anticipating this possibility, he had evidently decided that his countries of choice for banishment would include Britain, and therefore it would be sensible to prepare himself, in Siberia, by learning English. Accordingly, he devised his own method. First, he tabulated and learned all the nouns. Then he went on to the verbs, the adjectives, the syntactic rules, and so on. He concluded that this systematic approach would enable him, on arrival in London, to converse with the locals. As it happened, he was amazed to discover that not only could he not converse well, he could not converse at all, and still less understand what people said! This chapter will explore factors that are relevant to the learning of a language, as well as the teaching that can promote such learning. It will review research into the nature of learning and acquisition and then go on to consider current views on the nature of language instruction. These reviews may shed light on the alternative courses of action that Lenin might have adopted.

Learning and Learners

We will consider language learning first, since it has a more fundamental role. A number of preliminaries are unavoidable here. First, there is the issue of a critical period for language, that is, a period during which acquisition is different from other learning processes. It will be assumed that there is such a critical period. Robert DeKeyser has demonstrated clear age-on-arrival effects for ultimate level of proficiency for Hungarian immigrants to the United States, that is, the younger the arrival, the higher the eventual performance. This research is far-reaching in its consequences. It implies that subsequent (second) language learning is mediated by general cognitive processes, an interpretation that has important consequences for instruction especially.

The second underlying issue concerns the concept of a focus-on-form. Michael Long has argued consistently that when learners engage in interaction, it is natural to prioritize meaning, with the result that form does not obviously come into focus. As a result, for effective learning to occur, it is necessary to *contrive* a focus-on-form, but in such a way that meaning is not compromised or distorted. A focus-on-form approach is consistent with current conceptualizations within cognitive psychology regarding the functioning of limited capacity attentional and memory systems. We cannot attend to everything, and so attention has to be directed selectively, and memory resources, especially working memory, have to be used efficiently.

The third underlying issue is over whether what is learned (the representation issue) is implicit or explicit, and indeed whether the learning process is itself implicit or explicit (the transition issue). Allied to this is the question as to whether something that was initially explicit, e.g., a language rule or a structural pattern, can become implicit, or vice versa. The implicit-explicit distinction has largely replaced the earlier contrast between learning (explicit) and acquisition (implicit), and this realignment has been associated with a greater influence from contemporary psychology, and a strong interest in operationalizing the difference between implicit and explicit learning. Where people stand on this issue also has an important impact on different views of instruction.

Finally, by way of preliminaries, there is the question of the stages through which learners pass. It is useful to think of:

- Input processing strategies and segmentation
- Noticing
- Pattern identification, restructuring and manipulation
- Development of control
- Integration and lexicalization

Learners, of course, may be at different stages in this sequence for different parts of their developing language systems.

Each of these stages raises issues regarding the nature of second language learning. Bill VanPatten has argued that learners can benefit from being taught how to process input more effectively in order to focus on form. At the next stage, Dick Schmidt has developed the concept of noticing, arguing that before some aspect of language structure can be learned, it first has to be noticed, preferably with awareness. For Schmidt, the gateway to subsequent development

is attentional focus, since it can permit deeper processing. In taking this position, Schmidt is arguing against Krashen's ideas on naturalistic learning and the acquisition-learning distinction. Clearly, though, whether noticing triggers explicit or implicit processes, the next stage in development is that the element that is noticed should become the basis for the learner identifying some sort of structural regularity in the language. This might be a new pattern, or the complexification of an existing pattern, and is the phase that accounts for development in the interlanguage system.

To perceive a structural regularity in the target language, however, does not mean that it can be used. Interlanguage development may sometimes be sudden and complete, but most accounts of second language learning assume that first insight has to be followed by a process of gradually increasing control over a new form. During this process, it is assumed that slow, effortful, and attention-demanding performance, which may also be error-prone, is progressively replaced by less conscious, easier, automatic, and fast performance. In this, the skilled control that is achieved over language performance resembles learning that occurs in other domains. Researchers have been interested in exploring the conditions that can enhance this development optimally, as well as describing the course and speed of such learning. A number of researchers, such as Nick Ellis, use general laws, for example, the power law of practice, to describe such learning.

In previous years, it was generally thought that the development of a high degree of automatization and control would have been the end-point of the learning process. In the last twenty years or so, linked perhaps with the development of corpus linguistics, there has been a greater realization of the importance of formulaic sequences and idiomatic language. That is, rather than prefabricated language being a minor part of the psycholinguistic abilities of the speaker, they are now seen as pervasive and vital for real-time communication. It is assumed that highly competent language users rely on formulaic language to ease the processing or computational burden during ongoing language production, and to sound native-like.

Having explored these preliminaries at a more explanatory level, there are a number of theoretical accounts relevant to the nature of second language development. Obviously the first to consider here is Universal Grammar (UG). Researchers influenced by this approach take a range of different positions, for example, full transfer/full access, vs. for example, residual access through previous parameter settings. Basically, all approaches assume the importance for second language learning of the continued existence

of a Universal Grammar but differ over the impact that L1 learning has on this development. Lydia White proposed that it would be more appropriate to consider the role of UG in second language development as constraining the problem space, and requiring that L2 grammars be consistent with it, rather than expecting the L2 grammar to follow a deterministic path. In any case, in terms of relevance for instruction, there is the issue that UG researchers, necessarily, investigate features of language that are thought to be revealing about the operation of UG. In the main, these features, for example, the 'empty category principle,' the 'overt pronoun constraint,' do not follow the priorities of others, for example, language teachers. Second language research may therefore be more revealing for Universal Grammar than Universal Grammar is for language teaching.

An interesting contrast to UG that has emerged in recent years is William O'Grady's 'general nativism.' In this, there is acceptance, as with UG (which O'Grady terms 'grammatical nativism'), that human beings are 'wired' to perform learning tasks in a certain way, but O'Grady proposes that this nativist capacity is general in nature, rather than a module specialized for language. He suggests that the more general propensities (a) to operate on pairs of elements, and (b) to combine functors with their arguments at the first opportunity, are sufficient to account for the nature of language development and the structures that emerge. It is too early to evaluate this approach as yet, but it is interesting that there are slight affinities between it and that of another theorist, Manfred Pienemann and 'processability theory.' Drawing upon lexical functional grammar and Levelt's processing model, Pienemann takes as fundamental a performance-based incremental approach to language generation. He offers a different set of processing procedures and routines to O'Grady, for example, lemma access, the category procedure, etc., but he, too, then makes predictions about sequences in second language development. So in either case, the nature of the grammar that results, is seen as the consequence of processing procedures.

In contrast, there have also been proposals in recent years to account for second language development through connectionist architectures. These are networks of associations, involving several layers to connect inputs and outputs, i.e., containing hidden layers that serve as general-purpose learning devices. They are implemented through computer software, and this software can 'learn' and be tested. For example, it could take the input of a simple verb form in English and the output would be a past tense form. Such networks can be trained to produce highly accurate past tense outputs, for example, including

characteristic mistakes that second language learners make. There is nothing specifically linguistic about the networks, so they are used to support the claim that specialist modules are not required for languages to be learned. The best known example of a connectionist network applied to second language learning is the competition model. This uses cues such as animacy and word order to predict how well learners with different L1/L2 combinations will learn how to assign subject and object roles in sentences.

The approaches to learning covered so far have focused on individual mental structures and processes. But other approaches have been more concerned to situate learning within a social context, and to explore the potential that interaction provides to give learners useful data. One example of this is Long's interaction hypothesis. Assuming the inadequacy of input alone (i.e., positive evidence), Long focuses on the provision of negative evidence, i.e., evidence that a mistake has been made. He proposes that such evidence can be obtained within natural interaction. In particular, he proposes that particular sorts of interactive encounter, i.e., those in which there is negotiation of meaning, leading to feedback moves such as confirmation checks, comprehension checks, clarification requests, and especially interlocutor recastings of the L1 speaker's utterance, provide timely and personalized negative evidence without compromising the (vital) naturalness of communication. This approach is located within Long's proposals for the importance of a focus-on-form, since form is brought into focus incidentally through these conversational devices, enabling learners to attend to it and perhaps, at a later stage, incorporate the effects of such feedback into their interlanguage. There have been questions as to whether there is immediate uptake of recasts that are offered, but Cathy Doughty argued that immediate uptake may not be the most effective way to detect the influence of recasts on subsequent development.

Also concerned with interaction, but from a radically different perspective is sociocultural theory (SCT). Drawing on Vygotskian theory, the emphasis here is on the collaborative, unpredictable meanings that will develop through conversation, with each partner making contributions that can be taken up and extended by their interlocutor. Jim Lantolf argued that this is a fertile ground for second language development, and sociocultural theorists claim that tasks that generate lower negotiation for meaning indices (e.g., a discussion task) may provide other more useful scaffolding for language development, since they push learners to build meanings collaboratively, and to engage in more extended turns. Indeed, developing the notion of interaction, Merrill Swain

has proposed that output is vital for second language learning since it pushes learners to do things like notice gaps in their interlanguage; to explore and test out hypotheses; and to attain a metalinguistic level of processing.

We turn now to consideration of learner characteristics and differences. The remainder of this section on learning will cover language learning aptitude, motivation, language learning strategies, and personality. Earlier conceptions of foreign language aptitude, strongly associated with J. B. Carroll, proposed that there is a specific talent for language learning, consisting of four components; phonemic coding ability (the capacity to analyze sound so that it can be better retained); grammatical sensitivity (the ability to identify the functions that words fulfill in sentences); inductive language learning ability (the ability to take a sample of a language and extrapolate to further language); and associative memory (the capacity to make links between items in memory). This view of aptitude, underpinning older aptitude test batteries (for example, the Modern Languages Aptitude Test), was reasonably successful, since these batteries led to correlations of around 0.40 between aptitude and achievement test scores. It has not, however, had great recent influence, partly because it has been argued that this conception of aptitude is irredeemably linked to instruction, indeed particular forms of instruction, such as audiolingualism, rather than to informal and acquisition-rich contexts.

More recently, however, a reassessment of aptitude has taken place. A new aptitude battery has been developed, CANAL-F. The battery incorporates cumulative, thematized learning within the sequence of subtests. Aptitude has also been reconceptualized and linked with second language acquisition processes, following the stages outlined above (noticing, pattern identification, etc.), and this sequence can also be related to the constructs that are said to underlie CANAL-F, such as selective encoding (noticing) and selective transfer (inductive language learning ability and pattern restructuring). Complementing this, there have been studies that have linked aptitude information to acquisitional contexts. These studies have shown that aptitude generates correlations with informal and implicit learning conditions as well as explicit ones. Indeed, reviews of the available evidence demonstrate that predictive relationships emerge in both informal and formal settings.

Motivation has seen an even greater diversification of research. This area has been dominated by the work of Robert Gardner, whose analysis of motivation in terms of integrative and instrumental orientations has been fundamental. He has continued to publish and to extend his model of second language learning.

However, some earlier reviews of his work that called for a widening of the research agenda have led to different perspectives. There have been proposals for slightly different conceptualizations of motivational orientation, but essentially still within the Gardner framework (for example, proposals for knowledge, travel and friendship orientations, and suggestions that a world ‘modernity’ orientation is relevant).

There has also been a widening of the theoretical framework for motivation, with greater connections with mainstream psychology. For example, one perspective emphasizes linguistic self-confidence, which links with willingness to communicate research (WTC). This explores the reasons that underlie a learner’s readiness to actually engage in communication. There have also been some studies on motivational attributions, and these indicate the richness of attributional thinking on the part of language learners and the impact such thinking can have on the maintenance of motivational strength. Such studies also indicate how qualitative methodologies can be applied to the motivational arena.

Perhaps the greatest change in motivation research concerns the temporal dimension. Many have argued that motivation needed to be related more clearly to the classroom, and conceptualized dynamically, rather than in terms of static, unchangeable orientations. Zoltan Dornyei, for example, uses action control theory as a way of achieving this. He argues that one needs to explore influences before a task is done (for example, motivational orientations), different influences on motivational levels while a task is done (stimulating activities), and also the post-actional stage, where learners reflect after learning on the degree of success they have achieved, and its likely explanations, such as a personal lack of effort. Such posttask reflection may lead learners to make attributions that will influence future motivational levels. Interestingly, Gardner’s latest research also explores the issue of the malleability of motivation, and how some aspects of the Gardner model, such as integrative orientations, do not seem malleable, while other areas, such as attitudes towards the teacher, are.

Learning strategies research has continued to be researched intensively. Some early problems with this area continue to cause difficulty. One of these is the categorization of learning strategies, and area about which Ellis suggested: “definitions of learning strategies have tended to be *ad hoc* and atheoretical.” In response to this, Zoltan Dornyei and Peter Skehan suggested that one should operate with four main classes of strategy:

- Cognitive strategies
- Metacognitive strategies

- Social strategies
- Affective strategies.

They also draw attention to the way that within mainstream psychology, there has been a movement away from learning strategies and toward the term ‘self-regulated learning,’ which more generally captures the learners’ conscious and proactive contribution to enhancing their own learning process. Interestingly, though, there has been recent evidence based on a confirmatory factor analysis in an attempt to distinguish between the various models that classify learning strategies, and this suggests that Rebecca Oxford’s six-factor model (the above four, plus a separation of cognitive into cognitive and memory, and the addition of compensatory) best satisfied the data.

Perhaps the one other learner difference area where there has been interesting progress has been that of personality. Some researchers have tended to dismiss personality as the source of empirically-verifiable correlations with language learning achievement. However, if one focuses on extroversion, it appears that applied linguists tend to have done two things (a) they have not been conversant with current theories of personality, or of associated standardized forms of personality assessment, and (b) they have tended to focus on possible relationships between personality variables and learning. When personality assessment is carried out using contemporary and validated personality inventories, results are clearly more stable. In addition, consistent correlations emerge between such extroversion–introversion measurements and foreign language performance – not with learning but with, for example, tests of speaking.

Teaching

Some twenty-five years ago, when second language acquisition research first began to have an impact, the value of instruction itself came under question, since direct evidence of its beneficial effects was slender, and it was proposed that exposure to language (and incidental learning) was sufficient for interlanguage development to occur. An important review article by Michael Long, “Does second language instruction make a difference?” responded to these issues and evaluated the available research on instructional effectiveness. Long’s work was a meta-analysis – he evaluated, reanalyzed, and synthesized a wide range of studies and argued that the balance of evidence suggests that instruction does make a difference, and is associated with faster learning, and higher ultimate attainment. More recently, a major updated and extended meta-analysis has been published that demonstrates instruction does have an appreciable effect

on performance; that explicit instruction produced larger gains than an implicit approach, which was, in turn, significantly greater than for control group conditions; and that instruction is durable in its effects.

What John Norris and Lourdes Ortega, in this updated meta-analysis, did not set out to do is provide a detailed justification of how instruction works, or, what specific aspects of instruction generate the differences that are found. Consequently, it is not easy to point to evidence of optimal learning environments – we simply know that having instruction compared to not having instruction is a good thing. How this lack of a fine-grained understanding of the effects of specific instructional types will be resolved is not clear. One approach is to continue to use research designs that do explore methodological comparisons that would be recognizable by teachers. Alternatively, the question may need to be posed differently. As Cathy Doughty recommends: “Rather than at the level of ‘method,’ the operationalization of instructional treatments is now considered best analyzed psycholinguistically in terms of input-processing enhancements that facilitate L2 learners’ extracting forms and mapping them to meaning and function.” She discusses a range of techniques that might achieve this, examining them in terms of degree of obtrusiveness, and also relating them to the functioning of limited capacity attentional functioning.

The preceding discussion means that explorations of language teaching options cannot be conducted simply in relation to evidence. But of course teachers need to act, and any broader research findings and theories about learning are going to be only one of the influences on such actions. We will next consider the major issues that motivate debates about teaching. Most fundamental of all, perhaps, are the topics of syllabus and methodology. The former concerns what is taught, and is traditionally approached in terms of the units of teaching, as well as their sequencing. The latter is concerned with how whatever is taught is taught. As we shall see, there have been changes with respect to each of these, although it is a moot point as to whether these changes are more characteristic of the ‘chattering classes’ of language teaching professionals rather than what happens in most actual classrooms.

Until relatively recently – the early 1970s – there seemed relatively little controversy in syllabus or methodology. The units of syllabus were seen to be language forms, and their sequencing was subject to reasonable consensus. True, the criteria that were used to establish syllabus ordering were not entirely convincing (for example, buildability, frequency), but there was considerable agreement about a high

proportion of the ordering that was characteristic for the teaching of English, at least. This consensus was challenged during the 1970s and 1980s, and alternative proposals were put forward, with alternative units, such as functions and notions and lexical elements, and alternative classroom activities such as tasks and procedural syllabuses. Most radical of all, perhaps, was Candlin’s proposals for retrospective syllabuses, where the syllabus that is taught is the result of negotiation between the teacher and learners, building on the distinction between the plan for teaching and the classroom reality of what actually happens, which are not going to be the same thing. Chris Candlin has suggested that one can only really say what a syllabus has been *after* a course has taken place. There were also vigorous attempts to develop specific purpose syllabuses based upon the analysis of learner needs.

Interesting issues have also been raised about the feasibility and limitations of planning courses, and whether it is even worthwhile to use course books. There seemed to be strong moves to use meaning-units as the basis for teaching, and to bring the learner more centrally into decision making. But what is interesting is how this debate has lost vitality. Now there is much less debate on these issues, and, paradoxically, the solution has been something of a consensus to use forms of what are called ‘multi-syllabuses,’ where the early pages of a course book or syllabus document will contain a table indicating how structural units, functional units, context, themes and tasks are meant to exist in harmony, so that the syllabus can claim to comprise all the potential syllabuses in one. Even so, it would appear that some of the strands in a multisyllabus are more equal than others, and it is no surprise that the most dominant of these is the structural core.

There have also been discussions regarding what should be done within classrooms, and what methodologies are better. Significant reviews are available of the major contrasting methodologies, such as grammar translation, audiolingualism, functional-notional, and communicative approaches. Grammar-translation emphasizes written language and the use of rules (and exceptions) to construct sentences in a deductive manner. Grammar is preeminent and item-based vocabulary learning is extensive. Audiolingualism, in contrast, emphasizes the spoken language and teaches this inductively through stimulus-response-influenced pattern practice. Functional-notional and communicative approaches share a much greater emphasis on meaning and the use of (more) authentic materials. Functional-notional approaches use itemized meaning-units as a syllabus basis and are usually concerned with language use

and contextualized teaching. Even so, there is the possibility that functional–notional approaches, although using meaning units, can be associated with fairly traditional practice-oriented methodologies.

Functional–notional approaches were really the foundation for the development of a communicative approach to language teaching, which is now regarded as the orthodoxy in many parts of the world. Communicative approaches come in two strengths: weak and strong. The weak form is compatible with multisyllabuses and gives communicative activities an important role, since it is assumed that learners will need to work on the development of communicative competence, and that they will not be able to do this without engaging in realistic communication of individual meanings. This goes well beyond the production phase of the three Ps, and requires authenticity of language use and genuine interaction. However, the weak form can be associated with optimism that teaching materials can blend structure, function, and communicative activity to promote balanced and integrated progress. The strong form of communicative teaching, now associated with task-based approaches, regards task itself as the primary unit and then sees language as following the demands of the task, so that the role of the teacher is to respond to whatever language the task generates as important. Jane Willis described a methodology for approaching instruction in this way, in which a language focus is the last phase in teaching, after some new language has been made salient by the need to do a task.

Of course, these are not the only methodologies that have been used, and there are other ‘fringe’ approaches. There are also, for example, total physical response, the silent way, suggestopedia, and community language learning, although it is interesting to note that while each of these has its devotees, it can be argued that they are becoming even less central (cf. the change in the amount of coverage in the first and third editions of Harmer’s *The practice of communicative language teaching*).

The debates over methodology have been intense. In an attempt to make progress in these debates, in which distinctions between syllabus and methodology were not always clear, it has been proposed that it is fruitful to look at these issues in terms of approach (underlying theory), design (syllabus considerations), and procedure (methodology) and what goes on in the classroom, in order to characterize a broader concept of ‘method.’ In an ideal world, an approach to language teaching should balance all these things, but in practice, one of the three might dominate, somewhat at the expense of the others. Hence, with audiolingualism, the focus is on

procedure, as well perhaps as approach, but there is much less to motivate design. In contrast, one could argue that functional–notional approaches emphasized design, but with less emphasis on approach and procedure.

It is interesting now to reflect on these debates and the intensity they used to provoke. Two issues stand out. First, prevailing practice would generally be seen as a communicative approach to language teaching, or at least this is what would be said, even if what happens in any particular classroom might not indeed be communicative language teaching. The approach has become the general orthodoxy. Second, and probably more important, we have seen the emergence of the course book series. We are now in a position where the production of course book materials is big business and associated with the commitment of very considerable resources. These resources are directed at the preparation of the course book proper, the extensive piloting of material, the development of a wide range of supplementary and ancillary materials (including websites), even the development of associated tests. One consequence of these developments is that the role of the teacher is changed. There is less reason for teachers to devise their own materials and it is much more possible simply to ‘teach the book’ as the course book’s ubiquitous multisyllabus is followed.

An interesting way of exploring changes in language teaching is a comparison between two editions of the same book, Jeremy Harmer’s *The practice of English language teaching*. In addition to a great deal of common ground, there are some interesting changes. First, there is something of a retreat from grander ideas on syllabus and methodology, to a greater concern for techniques at a more micro level, and issues connected with classroom management. Interestingly, there is more emphasis on how to handle mistakes and how to provide feedback. Second, there is greater coverage of language itself, and of how it may now be studied through corpus analysis so that more realistic language is used. Third, there is a greater concern with course books. Coverage is provided about course book selection and how to work with a course book, changes that reflect the point made earlier regarding the greater domination of course book series presently. Finally, there is very significantly increased coverage of the role of technology in language learning, with complete chapters devoted to teaching using video, and educational technology. This last development is undoubtedly going to grow enormously in importance. There are now increasing numbers of books about the use of computers and the internet in language teaching, and leading journals such as *English Language Teaching*

Journal contain regular sections detailing useful Web resources.

Language teaching, happily, still has some active areas of disagreement and debate. There are interesting proposals regarding process syllabuses, where the role of the learner in negotiating what will happen in the classroom is recognized and fostered, even to the extent of allowing learners to influence the nature of assessment. This work nicely complements applications of sociocultural theory to second language acquisition, which also regards the joint construction of meanings as fundamental (although in this case more because it facilitates acquisition itself). Process syllabus proponents are perhaps more interested in the rights of learners to influence their instruction as well as the broader societal benefits that follow from learners who learn how to take personal responsibility in this way.

A second area for lively exchange concerns the role of tasks in language teaching methodology. Two sub-questions are relevant from this debate. First, there is the issue of how predictable tasks are in terms of the effects of task types and task implementation, for example, pretask planning, on the language that is produced. One response is to doubt any predictability because learners will negotiate their own interpretations in ways that reflect their own interests and desires, whereas another is to research these factors in the hope of providing evidence to assist teacher decision-making. Second, there is the issue that tasks have been attacked because it is proposed that what should really be the focus for teaching is grammar. In this view, tasks might be permissible as a form of language use after more conventional grammar teaching has taken place. It has been suggested that they should not be used as the unit of language teaching, or even regarded as a means to enable interlanguage to change and develop. In contrast, others argue that tasks provide a way for acquisition processes to be brought into the classroom and become the basis for learner-driven development.

A final area of debate within methodology concerns the issue of appropriateness. There have been general debates about the connections between language teaching – especially English language teaching – and imperialism. The argument is that the teaching of English is not a neutral activity, but contributes to the perpetuation of existing international power structures, and implicitly the downgrading of local cultures and power. At a much more specific level, Adrian Holliday has argued that there has been insufficient attention paid to local needs and to the different conditions that operate in many language teaching contexts, and that another form

of imperialism is the way methodologies devised in one set of circumstances are assumed to be relevant for wholly different contexts. At the broadest level, he contrasts two contexts and the imbalance between them. The first concerns approaches to language teaching developed for favorable circumstances (for example, Britain, Australasia, and North America, which he refers to, using the relevant initials, as BANA), a context in which individuals often pay fees for their instruction, are studying voluntarily, and in relatively small groups with good resources. In contrast, the second context, referred to as TESEP (*Tertiary, Secondary, Primary*) relates to state school education in the rest of the world, where there are usually large classes, with less favorable resourcing, different home-school relations, and learners who have no choice but to be in a classroom. They are also likely to be heading for a testing system that is less communicative in nature. Methodological options appropriate in the former context do not generalize easily to the latter, so more attention needs to be paid to local cultures, realism about local resourcing, and local educational traditions.

Conclusion

As the first section of this chapter indicated, the field of second language acquisition research has made a range of interesting contributions to our understanding of how languages are learned. There are alternative accounts available and regular research output. It can even be argued that the two subfields of acquisition/learning processes and learner differences are coming together for the first time, to the mutual benefit of each. We have also seen that language teaching is an area with considerable vitality. Teaching is still strongly influenced by language description, but the consensus communicative approach has meant that a range of activities focusing on meaning are also central, and that the quality of materials available (if not always their accessibility) has improved dramatically.

As a final point, it is worth making the observation that although the two areas of learning and teaching might reasonably be expected to have strong relationships with one another, in practice, they do not. Learning/acquisition tends to have a research emphasis, and while it does have relevance for teaching, this requires some extrapolation. Teaching, in contrast, while not without interesting research work, nonetheless emphasizes other criteria in establishing and justifying its procedures. It would be desirable to see this separation reduce in the future, for the benefit of both.

Second Language Listening

Introduction

It was not until well into the second half of the 20th century that second language listening was widely recognized as a skill that could and should be systematically developed and assessed by those teaching a second language. Whereas earlier scholars such as Henry Sweet and Harold Palmer had stressed the importance of teaching the spoken language, in their view such teaching was to be based on “the science of phonetics,” which effectively meant that the aspect of the spoken language actually taught was its pronunciation. It seems that these scholars supposed that, if you could pronounce the target language reasonably well, it must follow that you would be able to understand it when you heard it spoken. So, in early work on listening comprehension based on the structuralist tradition, it was assumed that the main problems in second language listening would be a mirror image of problems with pronunciation. Students were systematically taught to identify differences between those sets of vowels or consonants in the target language that a contrastive analysis of the phonological systems of the L1 and L2 predicted would be difficult for the L1 speakers to distinguish in L2 speech. Students listened to triplets of words, such as *bit bit beat* or *try dry try*, and were required to identify which of the three words was different from the other two. They listened to sets of words with similar consonantal and vocalic structure but different stress patterns and identified those with different stress patterns. And they listened to phrases like *the pink one* uttered with either falling or rising intonation and identified the one with rising intonation as a question.

With the advent of mass tourism in the 1960s, the gulf became glaringly apparent between being able to identify a sequence of words spoken slowly and carefully in the foreign language and being able to identify words in the acoustic blur of normal conversational speech. As Wilga Rivers (1968: 135) remarked, emphasis in language teaching had hitherto been placed on students’ production of the language, disregarding the fact that communication takes place between (at least) two people. She suggested that the primary difficulty for a traveler in a foreign country was not the problem of making himself understood but of being unable to “understand what is being said to him and around him”.

On the rare occasions when students were invited to listen to a tape to understand the content of what

was said, they typically listened to a text that consisted of a narrative or discursive text read aloud slowly and distinctly by a native speaker. After listening to the tape, they were asked questions on the content. The questions, often as many as 10 or more, concerned information spaced at roughly equal intervals through the text, following the format widely used in ‘teaching’ the comprehension of the written language. Consider what these second language learners were being required to do: “treat all spoken language as primarily intended for transference of facts ... listen with a sustained level of attention, over several minutes to spoken language ... interpret *all of it* ... commit that interpretation to memory ... answer random, unmotivated questions on any of it” (Brown and Yule, 1983: 60). Sophisticated adult native speakers often had difficulty in recalling some of the trivial detail that such ‘comprehension questions’ addressed. For most second language learners, the experience was negative and demotivating.

The challenge since the 1960s has been to help students identify words in the stream of speech and to equip them with strategies to enable them to interpret the content of utterances in the relevant context of utterance and to work out what speakers mean by what they say.

Bottom-up Interpretation

It seems clear that structuralists were correct in claiming that being able to identify words in the stream of speech is fundamental to understanding what a speaker is saying. In some genres of speech, notably in relaxed conversation, where the focus is on the establishment or maintenance of social relationships, it may not be necessary to identify all the words that are spoken but, to participate meaningfully in the conversation, it is essential to identify at least those expressions that indicate the topic of the utterance and what is said about that topic. In primarily transactional genres, on the other hand, where the transfer of information will have some effect in the world, it may be essential to identify even the detail of those unstressed grammatical words that you can often afford to leave only vaguely guessed at in social conversation. When you are listening in your first language, you tend to be quite relaxed about how much you can afford not to fully interpret. In a second language, particularly in the testing situation of a classroom, it is hard not to panic if you realize that a series of unidentified words is rushing past your ears.

It is sometimes suggested that, in order to identify words in the stream of speech, it is necessary to be

able to identify all the consonantal and vocalic oppositions that occur in the accent of the target language that students are being exposed to. This is a counsel of perfection. We should remember that in any accent of English, some of the oppositions found in other accents will not occur. Thus, standard American English does not distinguish between the words *balm* and *bomb*; young speakers of southern British English ('RP') do not distinguish between the words *paw*, *pore*, and *poor*; Scottish English does not distinguish between the words *cot* and *caught*, *cam* and *calm*, or *pull* and *pool*; Yorkshire English does not distinguish between the words *put* and *putt*; and London Cockney English does not distinguish between the words *sin* and *sing*, *thin* and *fin*, or *that* and *vat*. Yet, on the whole, speakers of different accents of English understand one another's speech well enough, even though in their own accent they do not make exactly the same set of phonological distinctions that their interlocutor makes. Second language learners are likely to encounter speakers from a range of different English accents and need to learn to identify the basic distinctions that are maintained in stressed syllables in all English accents, rather than spending much time on rare sets of oppositions that do not occur in most accents and which, even there, may carry only a low functional load. Whereas courses in pronunciation will normally be based on only a single native accent, courses in second language listening need to be much less constrained and to be relevant to a variety of major English accents.

There is obviously a significant difference between encountering words in the written and spoken forms of the language. In the written form, spaces between words unambiguously demarcate individual words. A major difficulty in interpreting the spoken form of a second language lies in determining where word boundaries occur. It is not always appreciated that crucial information needed in the task of segmenting the acoustic blur of the stream of speech lies not only in discriminating between phonological oppositions but also in identifying the phonologically conditioned variables that characterize particular consonants when they occur initially or finally in a word or stressed syllable. For historical reasons, much has been made in teaching English as a second language of the 'aspiration' (delayed voice onset time) that follows the articulation of a voiceless stop when it is initial in a stressed syllable. On the other hand, the glottalization that precedes the articulation of the same set of phonemes in the coda of a syllable in most accents is typically ignored. Yet each feature is equally informative in identifying relevant parts of word structure (Brown, 1990: Chap. 2). Similarly

much has been made in British ELT of the distinction between palatalized ('light') and velarized ('dark') /l/, without noting the generalization that the structure of the syllable in the RP accent is always more palatalized in the onset and more velarized in the coda of the syllable, a fact that affects the articulation of all consonants in these positions. The effect is most easily heard in sonorants and continuants where syllable-initial (onset) consonants will be heard as more palatalized, and hence higher in pitch, than syllable-final (coda) consonants. There are, of course, accents whose syllables are differently structured: the English of Glasgow has velarized consonants initially as well as finally, and Welsh English has palatalized consonants finally as well as initially.

Much more generalizable across accents than these palatal/velar subtleties is information about those phonotactic constraints that are helpful in identifying syllable and word boundaries, information that is sadly underexploited in the teaching of second language listening. For example, if an ESL listener hears a sequence /ml/ in the stream of speech, it is relevant to know that, since this cannot form an onset cluster in a syllable of English, it cannot mark the beginning of a word. The /l/ must be syllable initial, which means that the /m/ must be final in the preceding syllable; the significance of this fact is that where there are syllable boundaries, there are potential word boundaries (Cutler and Norris, 1988). An essential requirement is to learn to identify and to pay attention to the stressed syllable of words, since this is the syllable that is most reliably clearly articulated. In the stream of speech, a great deal of the phonological information that is available when words are pronounced slowly and clearly in citation form is routinely lost, particularly in unstressed syllables. Unstressed syllables are frequently elided, particularly when they occur as one of an unstressed sequence (for instance, in words such as *library*, *governor*, *extraordinary*). Processes of elision and assimilation take place across syllable boundaries and radically alter the familiar features of the citation form. Such processes occur densely in normal, informal speech whose relevance for learners is much greater now than it was pre-1970 since this type of speech is used in a much wider range of situations than it used to be. It is not only found in informal conversational contexts but is regularly heard on radio and television (even in news broadcasts, once models of slow, carefully articulated speech) and is standardly used in academic lectures and in public speaking more generally. (Harris (1994) and Shockey (2003) gave detailed accounts of these processes.)

I have suggested that a crucial component of second language listening is identifying words

correctly. More to the point may be identifying the larger, prefabricated structures of which so much spoken language is constructed. Wray (2002) reviewed an array of studies that demonstrated the crucial significance of such structures, particularly in the early stages of learning a second language. It seems likely that many expressions are, initially at least, learned as unanalyzed chunks. Other expressions may be incorrectly analyzed (as in the case of the L2 learner of French who analyzed the spoken version of *chocolat* as *chaud cola*). In many cases, it may be that such expressions are stored and used quite effectively until eventually confrontation between spoken and written forms (or the utterance and the world) leads to a reanalysis. The acquisition of lexis, and of formulaic expressions in particular, is still the subject of extensive research.

Having identified (some of) the expressions in an utterance, the listener needs to order them into chunks that can be understood as syntactically structured and co-interpretable semantically. Just as the written language uses punctuation and layout to indicate the organization of discourse, there are various signals in speech, for instance, intonation, slowing down, and pausing, that indicate the boundaries of chunks of speech that need to be co-interpreted. In most accents of English, the beginning of a new sentential structure is typically indicated by being placed relatively high in the speaker's pitch range, and the rest of the structure is included within the overall contour that follows. The end of the structure is usually marked by being uttered at a lower level in the pitch range than the onset and is often followed by a pause. Internal sentential boundaries may be marked by shorter pauses and sometimes by variation in pitch height or direction (cf., Ladd, 1996).

Where spoken language differs dramatically from written language is in the scale of interruptions, modifications, and use of interpersonal markers in its production and in its reliance on the present context of utterance to constrain possible interpretations by the listener. Most speakers have had the experience of interrupting themselves, pausing, reconsidering, planning again, beginning to express themselves in one way, and then immediately modifying what they have just said. Unlike writers, they cannot undertake such operations secretly, without the interlocutor knowing. Second language learners unused to listening to spontaneous speech that has not been previously at least partially planned are in danger of having their attention distracted from the message by material that is introduced as part of the planning process. Often the changes speakers make are marked by interpersonal and modal expressions such as *well*, *erm ... I mean*, *so ... you see ...*, *if you get my*

meaning ..., *as far as I'm concerned ...*, *I think ...*, *I'm sure ...*, phrases that disturb the smooth flow of a sentential structure at both a syntactic and an intonational level. A feature of spontaneous conversational speech that second language learners need to become accustomed to is how such universal features of spoken language are managed in the second language.

As speech plays such an important role in interpersonal relationships, its production is often modified by paralinguistic features that express the attitude of the speaker toward the listener and/or toward what is being said. English speakers who are being particularly polite to the interlocutor often speak higher in their voice range, relatively softly, and with a 'breathy' voice, whereas those who are being aggressive typically speak lower in their pitch range, more loudly, and with a 'harsher' voice quality. Speakers who are being sympathetic or kind speak low in their voice range, slowly, and typically with a 'creaky' voice. Whereas it seems plausible that basic human emotions such as fear, anger, or timidity are expressed similarly in all languages, it seems probable that attitudes that are more culturally conditioned are more likely to be variable in their expression across languages. Second language learners, at quite an early stage in their exposure to tapes and videos of L2 speakers interacting, might profitably pay attention to paralinguistic features of speech in order to identify whether speakers are agreeing or disagreeing with each other, being polite or aggressive, or friendly or unfriendly, long before they can understand the linguistic details of what is being said (Brown (1990), summarized in Rost (2002)).

Interpretation and Inference

Clark and Clark (1977: 45) drew a helpful distinction between 'constructing an interpretation' and 'utilizing an interpretation,' drawing attention to the fact that, in everyday life, we use language to get things done. In doing a crossword puzzle, we might construct an interpretation without putting the interpretation to further use but most speech is functional, either to interact with someone socially or to transfer or extract information. This implies that there is more to the interpretation of an utterance than simply identifying words, syntactic structures, and thin semantic meanings; we must infer what the speaker who produced the utterance intended to achieve by it. The term 'interpretation' reflects this process better than the term 'comprehension.' To have comprehended an utterance suggests a total, correct product now present in the listener's mind. For a listener who is trying to understand a decontextualized utterance

in a language test, a translation equivalent of the thin semantic meaning may yield a judgment of 'correct' but, as Goffman (1981: 28) remarked, "the mental set required to make sense of these little orphans is that of someone with linguistic interests" rather than someone who is using language purposefully. It might be supposed that a total, correct product could be achieved in understanding short, banal utterances such as *what is the time?* But even such a familiar utterance may have been produced by the speaker primarily to bring about an awareness of the passage of time on the part of the listener, an intention that the listener may remain unaware of even after having produced an apparently appropriate translation. 'Interpretation' gives a better impression of the riskiness of the listener's effort to understand what the speaker means by producing the utterance and it gives no impression of finality – once constructed, an interpretation is not fixed and immutable but may subsequently be modified. It is because, in most genres, there can be no single 'correct' interpretation of what is said that some scholars question the possibility of measuring or assessing the degree of a student's 'spoken language comprehension' (issues discussed in Shohamy (1996); Spolsky (1994)).

To arrive at an interpretation, the listener needs to make inferences at many levels. To begin with, the listener may need to infer the identity of words not clearly heard but which would make sense of the utterance. Then, the effect of the immediate verbal context on the sense (meaning) of words must be taken into account. For instance, the word *red* prototypically denotes a strong, saturated red hue and the word *face* prototypically denotes the configuration of eyes, nose, mouth, and chin that would be represented in a child's drawing. However, once these words occur in the phrase *red face*, *red* must be interpreted as denoting a pinky, blotchy color, whereas *face* will draw attention particularly to the cheeks and perhaps the forehead but certainly not the eyes or mouth. The listener must infer which of a wide range of senses is appropriate in a given verbal context. For a second language listener, particularly one who has learned the foreign words in terms of one-word translation equivalents, extending the interpretation of a word well away from its central translational sense requires considerable confidence since it is obviously an operation fraught with risk (Færch and Kasper, 1986).

The issues of syntax, of combining words in one syntactic structure rather than another, and of the choice of syntactic structure having any effect on interpretation have been curiously neglected in cognitive models of comprehension. Most accounts of

discourse meaning simply ignore the nature of the syntactic structures selected by the speaker and produce representations of discourse meaning consisting of a set of abstract semantic 'propositions' from which all specifically syntactic information has been expunged. A few writers have insisted on the significance of syntactic structure in determining how the semantic content of an utterance is understood (e.g., Brown, (1994); Levinson (2000)). Halliday (1978) pointed out the disruptive effect on the listener's presuppositional coherence of using inappropriate syntactic structures (consider which is the most appropriate radio commentary on a ceremony: *The sun's shining. The day's perfect.* versus *It's the sun that's shining and the day that's perfect*). Davison (1980) noted the effect on interpretation of using passive rather than active constructions in some circumstances, and Sanford and Moxey (1995) have drawn attention to the inadequacies of any account of interpretation based solely on propositional representation. It is far from clear why a language should develop different ways of expressing the same propositional content if using a different syntactic structure has absolutely no effect on meaning. Rather little experimental work has been conducted on the effect on interpretation of varying syntactic form but at least we should note that a competent listener would need to draw inferences when an unexpected syntactic structure is employed: compare the effect of *He certainly spoke to her* with *She was certainly spoken to by him*.

The Context of Utterance

It is a truism that spoken language typically relies heavily on context for its interpretation. There is a widespread view that speakers and listeners 'share' the context of utterance. Yet a moment's thought reminds us that speaker and listener can usually see each other's face and facial expression but not their own, and each of them has private interests, perceptions, judgments, and prejudices and brings to any interaction different hopes and expectations for its outcome. As Johnson-Laird (1983: 187). remarked, "the notion of the context overlooks the fact that an utterance generally has two contexts: one for the speaker and one for the listener. The differences between them are not merely contingent but... a crucial datum for communication". I shall consider three aspects of context from the point of view of the listener: external context of situation, social context, and textual/discoursal context. Each of these aspects of context interacts and overlaps with the others, more or less obviously in different genres (Brown, 1998).

The External Context

Utterances are produced in a particular place and at a particular time. Much of what is said will be assumed to be relevant to the place and time of utterance. If someone comes into a room, shivers, and says *It's cold*, the listener will understand that the comment applies to the current place and time – if not to the temperature within the room, then to the local external temperature. If I, in a temperate country, say in winter *It's warm today*, I mean that it is relatively warm for this locality at this time of year, not that it is as warm as it might be in August or in Singapore. If the speaker says *She's coming on Monday*, the listener will assume that the relevant 'Monday' will be the next one after the day of utterance. If the conversation is about 'the president,' 'the doctor,' or 'the school,' the listener should assume that it is the participants' current, local president, doctor, or school, if no contrary information is given. Conversations will, by default and in the absence of contradictory information, be assumed to be relevant to 'local' conditions, where 'local' can be interpreted as widely as *here* can be interpreted in *here in my hand*, *here in this room*, *here on this street*, *here in this town*, *here in this country*, and so on.

A concept of 'appropriate behavior,' which may differ in different cultures, will set limits on what it is appropriate to say and how it is appropriate to say it in particular places and at particular times. There are appropriate greetings for different times of day, for meeting, and for parting. There are some places, places of worship, for instance, where some topics or manners of speaking would be judged inappropriate. If I have a trivial message for you about the postponement of some distant future event, it would be inappropriate for me to come to speak to you about it in your hotel room at midnight, invading your personal space and possibly awakening you from sleep. If, in defiance of convention, I were to insist on speaking to you in such circumstances, you might well infer that I meant more than I was overtly expressing. The subtleties of contraventions, deliberate or intentional, of conventions governing types of utterance appropriate to particular external contexts are peculiarly difficult for second language learners to interpret with any confidence without extensive experience of the culture where the second language is used.

The Social Context

For the listener, the most significant figure in the social context is the speaker, and the significant relationship is that between speaker and listener. Whether the speaker is speaking to a group of listeners or

shaping the utterance for just one listener, the speaker must make judgments about how far they will share what Clark called "communal lexicons" (1998: 60–87). Communal lexicons, Clark suggested, are built on such social features as shared nationality, education, occupation, hobbies, language, religion, age cohort, and gender. The more social features that the speaker and listener share, the more the speaker can rely on the listener being able to understand specialist vocabulary. Where speaker and listener share an occupation, suppose both are ship's engineers, even where the listener is a second language learner, they are likely to be able to negotiate the senses of technical terms with some confidence that each understands what the other is speaking of as long as the listener feels relaxed and is able to think clearly. However, when the speaker is the dominant participant in an interview that is communicatively stressful for the second language learner, for instance, when the learner is a junior doctor being interviewed for a job by a senior member of the profession, the ability of the listener to negotiate a shared understanding of a term may be curtailed, which may result in a breakdown of communication. For nervous students in examination conditions who are exposed to tapes of speakers with whom they share few, if any, of Clark's social features, only the most self-confident of students are likely to arrive at an adequate interpretation in the lottery of a speaker, or speakers, talking on a quite unpredictable topic that may be distant from any of the student's own interests. It will always be the case that a second language learner will have least difficulty in understanding language that the speaker is sympathetically shaping for that particular individual, taking account of the learner's current state of control of the second language and anticipated knowledge of the topic.

When listening to speakers from their own speech community, listeners will often make stereotypical judgments about the speaker on the basis of the speaker's self-presentation in terms of dress, hair, posture, and what the listener knows about the speaker's occupation. Such stereotypical judgments may influence the listener's interpretation of what the speaker says. If asked in the street what the time is by a smartly turned-out passer-by as opposed to one who gives the general impression of having just stumbled out of bed, different listeners may respond with different degrees of helpfulness in each case. If the listener hears *This is yet another example of hard work by the left* said by a left-wing politician, the listener will infer that the expression is used positively and appreciatively, but if the very same remark is uttered by a right-wing politician, the listener will infer that it is used negatively and critically.

Second language listeners may feel uneasy about importing stereotypical knowledge of the world from their own culture into interpreting what is said in another language.

They may also fail to notice when they have not properly understood what someone says, as young L1 listeners have been shown to do in their own language (Markman, 1981) or blame themselves for not having understood when native speakers express the content of their message inadequately. Robinson (1981), working with native speakers of English, showed young children who hear elliptical or ambiguous messages from adults may be 'listener blamers,' who attribute their difficulties in understanding such messages to their own inadequacy, rather than 'speaker blamers,' who are capable of recognizing that the speaker has produced a confused and confusing utterance. If second language learners hear a native speaker assert something that the listeners cannot make sense of, like 'listener blamer' children they may believe that they have not interpreted what the speaker said correctly, simply because they are reluctant to question the authority of a native speaker.

The Context of Discourse

The discourse context is created by whatever the conversational participants are currently paying attention to and by what has already been said on the topic. It is the structure of what has already been established in the discourse context that allows the listener to determine what anaphoric expressions refer to and what, within the discourse world, new expressions refer to (Gernsbacher, 1990; Smith, 2003). How much the listener must carry in memory from the previous discourse varies with the type of genre at issue. In genres such as instructions on how to complete a task, where each instruction is followed by a pause while the listener completes that step in the task, there is minimal burden on memory. Instruction tasks may be made easier by limiting the number of parts or participants and making them clearly distinct from one another. Narrative genres, where an understanding of what is happening now depends on your understanding of what has happened earlier, are likely to impose a greater burden on memory. Again, narratives can be simplified if events are narrated in the order of occurrence ('*ordo naturalis*'), if the number of participants is limited, and each participant is physically clearly distinguished from the other participants (Brown, 1995). The more complex the task, the more difficult it is to arrive at a secure interpretation, culminating in the problems of following abstract arguments in academic lectures (Chaudron, 1995).

Listening as 'Input' to Second Language Learning

When we consider the complexity of the demands made on the learner listening to a second language, it seems truly remarkable that such input can form the basis for learning the second language. Nevertheless, it is clear that to a greater or lesser extent, in different contexts of acquisition, some learners do successfully learn to control a second language to an impressive extent, largely from absorbing aspects of spoken input while simultaneously putting that input to use in constructing an interpretation of what a particular speaker intends to convey on a particular occasion of use. How this is achieved is the subject of extensive speculation in the second language acquisition literature (for a useful critical overview of the literature and an initial stab at a theoretical approach that distinguishes between the procedures of processing language for meaning and the processes of language learning, see Carroll (1999)). The most promising research thus far on this topic is that concerned with the acquisition of lexis, given spoken input (see, e.g., Ellis and Beaton (1993); Vidal (2003)).

Semantic Change: the Internet and Text Messaging

A Deumert, Monash University, Victoria, Australia

Electronic Communication: Efficiency and Expressivity

Since the 1980s, computer technology and mobile technology have given rise to various forms of text-based, electronic communication: e-mails, news-groups, chatrooms, and, more recently, blogs (web logs that function as on-line diaries) and text messaging (Short Message Service, SMS). The language used in electronic communication has been described as a hybrid, showing both speech-like and writing-like features, as well as features that are unique to the digital medium and are, to some extent, the result of its technological restrictions. For instance, slow modems, limited bandwidth, costs, small screens, and typing speed are often cited as reasons for the

preponderance of abbreviations in text-based electronic communication (cf. Baron, 2000; Shortis, 2000; Crystal, 2001).

The communicative need to use language efficiently within the constraints of the medium is complemented by the users' desire for conceptual and communicative expressivity (on efficiency and expressivity in semantic change cf. Geeraerts, 1997: 102–108). Crystal (2001: 67) has highlighted the "strong, creative spirit" that characterizes the language of Internet users: "The rate at which they have been coining terms and introducing playful variations into established ones has no parallel in contemporary language use." Linguistic creativity and playfulness can be described as conversational maxims of electronic communication and are most noticeable in recreational contexts (such as chatting and texting; Danet, 2001; Crystal, 2001: 168–170). Other conversational maxims (politeness, relevance, truth) can at times be suspended (or at least take

second place; cf. Wallace, 1999: Chap. 3, on deception, masquerades, and lies on the Internet). Innovative in-group language use and a predilection for speech play was already a defining characteristic of those pioneer Internet users who engaged with the culturally still uncharted medium in the early 1980s. Raymond (2003) comments, e.g., on the popularity of form-vs.-content jokes among hackers (a person who enjoys exploring the workings and capabilities of programmable systems) and cites the tradition of ‘hacker punning jargon’ as an example. (‘Hacker punning jargon’ is the *ad hoc* use of intentionally transparent puns: FreeBSD → FreeLSD or IBM 360 → IBM Three-Sickly.)

Some Aspects of Semantic and Lexical Change in Netspeak and Texting

Users of electronic communication, despite their geographical dispersion, form a relatively cohesive, sub-cultural group and have been described as a ‘virtual speech community’ (Paolillo, 1999). Much linguistic work has concentrated on documenting the in-group national and international vocabularies that are used in electronic communication. The six standard categories of semantic change (cf. Traugott, 2000) can be identified in the specialist Internet lexicon (or jargon) that has its roots in hacker usage:

- Broadening/Generalization/Extension: *grep*, a UNIX command meaning ‘Get REpeated Pattern,’ is now used widely as a verb with the meaning ‘to search.’
- Narrowing/Restriction: *banner* (top-centered graphic on a webpage), *to compress* (to reduce data size through the application of a mathematical algorithm).
- Amelioration: *nerd*, *geek* (which have acquired highly positive in-group connotations), *a hack* (a good and clever piece of work).
- Pejoration: *tourist* (an uninvited and usually non-participating guest on a discussion group), *random* (has a pejorative meaning of ‘unproductive’ ‘undirected,’ e.g., ‘he is a random loser’).
- Metaphor: *information superhighway*, *web-surfing*, *nipple mouse*, *gopher* (a software program designed ‘to gopher’ through information).
- Metonymy: *a suit* (someone involved in information technology who habitually wears suits and works in management, distinct from a real programmer or ‘techie’; pejorative), *vanilla* (‘ordinary’ < vanilla ice cream, the default flavor in many countries, e.g., United States, United Kingdom).

Acronyms and abbreviations are a salient feature of what Crystal (2001) has called Netspeak, e.g., IRL ‘in

real life,’ AFAIK ‘as far as I know,’ and BFN ‘bye for now.’ Media citations (from movies and computer games) have long been common in the in-group language of hackers and are moving into mainstream Netspeak: ‘all your base are belong to us’ is an expression used to declare victory or superiority (from a 1991 computer game; the citation spread through the Internet in 2001); ‘and there was much rejoicing’ can be used to acknowledge an accomplishment (from the movie *Monty Python and the Holy Grail*). Overlexicalization and the clustering of synonyms is another characteristic feature (e.g., *nick*, *handle*, *screen name*, and *pseudo* are all used to refer to the pseudonyms used by participants in chatrooms or newsgroups), as is the on-going creation of portmanteau neologisms (*netiquette*, *newbie*, *progasm*, *screenagers*, etc.). There are also conventions for the encoding of prosody and paralinguistic meaning: emoticons (smiley icons such as :-)), the use of capitals (to indicate shouting), and repetition of letters (for emphasis) are used to disambiguate written messages.

With regard to derivational morphology: the *e* prefix and the *bot* suffix (from ‘robot’) have established themselves as productive morphemes (*e-loan*, *e-government*, *e-cards*, *e-books*, *annoybot*, *mailbot*, etc.). In inflecting languages, such as German, a new and productive lexical class has emerged in the context of chat communication: nonfinite verb-last stems. These are used by participants to describe actions that are performed in the context of the conversation. The action descriptions are inserted in asterisks: **away sei** (*away be*); the full German infinitive of ‘to be’ is *sein*), **schnell zu dir renn** (*quickly run to you*); the full German infinitive of ‘to run’ is *rennen*; cf. Schlobinski, 2001). Verbal stems (*schluck* ‘swallow,’ *gäh* ‘yawn’) have long been used in comics and also colloquially in German youth language. In English, on the other hand, action descriptions such as **nod** and **sigh** are structurally ambiguous and not necessarily identifiable as stems; moreover, inflected forms such as **shakes hand** are not unusual in English chat communication (Werry, 1996).

The lexical structure and character of nicknames (‘nicks’) is another aspect of the linguistics of Netspeak. In terms of semantic preferences, Bechar-Israeli (1996) identified six main semantic fields from which nicks are drawn: self-descriptors (<shydude>, <Dutchguy>, <irish>); technology (<Pentium>); real-world objects (<froggy>, <tulip>, <cheese>); play on words and sounds (<kukyMNSTR>, <whathell>); famous characters (<Elvis>, <Barbie>); and sex and provocation (<fuckjesus>, <sexpot>).

The language of text messaging/texting, which has become a popular form of interpersonal

communication from the mid-1990s, is partially based on Netspeak, but shows a more radical use of abbreviations (e.g., 'it's prty low 4 sum 1 2 dump their b/f or g/f by sms' 'it is pretty low for someone to dump their boyfriend or girlfriend by sms'; special conventionalized abbreviations are also used in SMS, e.g., SWDYT 'so what do you think?'). The trend toward letter reduction (mostly achieved through a technique called 'consonant writing') and a generally telegraphic style have usually been interpreted as a response to the limited number of characters (max. 160) per message, and the small and awkward keyboard. They have since developed into a characteristic feature of the genre. It is not yet clear how technological innovations, such as predictive text software (which 'guesses' words after only a few key strokes), and market-related changes, such as the introduction of flat rates (rather than charging users per character), have affected (and will affect) the language of texting.

The Meanings of LOL: Semantic-Pragmatic Change in Electronic Communication

A well-known type of semantic-pragmatic change is subjectification, that is, the overall tendency for speakers/writers to construct new meanings on the basis of conversational implicatures reflecting speaker attitude or intention (cf. Traugott, 2000). In Internet Relay Chat (IRC), subjectification of meaning can be observed in the case of the popular abbreviation LOL/lol. The original propositional meaning of LOL is 'laughing out loud' and as such it can be used in response to, for example, a successful joke or an amusing story. This usage is indicated by metalinguistic comments such as 'I type it in after something funny is said ... and I am laughing.' However, LOL, which has the structural advantage of shortness (i.e., it can be typed quickly), has been recruited and conventionalized by IRC users to express a range of discursive and interpersonal meanings (on laughter as a contextualization cue in spoken conversations; cf. Adelswärd and Öberg, 1998).

(1) LOL can be used as a discourse marker. This usage is illustrated in Example 1 (from a German chatroom, #Berlin), where <mib> closes his turn (a factual question addressed to another participant) with LOL, inviting a response from the addressee. The meaning of LOL in this example can be glossed as 'I have finished my turn, please answer my question.' (The spelling in Examples 1–4 is that of the original transcript and has not been corrected by the author of this paper.)

Example 1: #Berlin (8/7/2002)

<mib> kommst du eigentlich zum rl-treffen? ('will you come to the rl ('real-life')-meeting')
<mib> lol

(2) LOL can also be used as a supportive back-channel and as a means of establishing rapport between participants (emoticons can take on similar pragmatic and interactional meanings; cf. Crystal, 2001: 38). The following extracts come from two South African chatrooms (#Afrikaans; #India) and a German chatroom (#Berlin). In Example 2, <perfume_girl> uses LOL as an interpersonal modifier to soften her rejection of <Pyro>; her use of LOL fulfills pragmatic functions of hedging and face-saving. In Example 3, LOL is used in the context of a virtual drinking game. It functions as an emphatic textual marker and creates emotional and interactional coherence (cf. Herring, 1999). In Example 4, <toxisches_ei> ('toxic egg') uses LOL (as well as a positive emoticon) in response to the comment by <|Phylax|schule|>. The use of LOL is followed by supportive spoken-language discourse markers (*naja*, *hmm*).

Example 2: #Afrikaans (8/7/2002)

[1] <perfume_girl> sorry oom ('uncle')
[2] <perfume_girl> better luck next time
[3] <perfume_girl> lol
[3] <Pyro> ek is skat ry ('I am super rich')
[3] <perfume_girl> if u know what i mean
[4] <Pyro> help dit? ('does this help')
[5] <perfume_girl> lol
[6] <perfume_girl> nee ('no')
[7] <perfume_girl> sorry
[8] <Pyro> damnit

Example 3: #India (26/7/2002)

[1] <Renzo_ReXXXeL> what did he say?
[2] <PsYcHoMiKe> ehehe
[3] <MizHOttie> lets drink!
[4] <Miz_KeWL> LOL!
[5] * Miz_KeWL downs it!
[6] <MizHOttie> LOL!
[7] <MizHOttie> lol, wat he say

Example 4: #Berlin (19/8/2002)

[1] <|Phylax|schule|> beio uns ist der gk deutsch
 sewerer als der lk deutsch ('here (at our school)
 O-level German is more difficult than A-level
 German')
[2] <toxisches_ei> lol :D
[3] <toxisches_ei> naja
[4] <toxisches_ei> hmm

In the examples given above, LOL no longer has a clear propositional meaning. It appears to be 'dese-manticized' or 'bleached' and is used as an interactional device that allows individuals to claim the floor, to express a range of interpersonal meanings

(hedging, face-saving), and to provide supportive back-channeling and textual cohesion in the ongoing conversation.

(3) LOL can also occur as an adverb (expressing connotations of affection; cf. Example 4) and has developed a number of variants (*lolol*, *lololololo*, *lölchen* 'little lol' in German chats, *ol*, *olo*).

Example 5: #Berlin (17/7/2002)

<[c]hrono> mib du bist so lol :) ('mib you are so lol')

(4) Finally, the propositional meaning of LOL is increasingly and creatively deconstructed by Internet users, and a range of alternative meanings have been promoted in various on-line forums: 'lists of links,' 'lots of love,' 'lots of luck,' 'love on-line,' 'little old lady,' 'lovingly ornamented long-johns,' 'leagues of lemmings,' 'love of libraries,' etc.

Conclusion: Diversity of Usages

There is a constant tension between global and local practices in electronic media, and although the influence of, in particular, American English is paramount, local usages and variations persist (Danet and Herring, 2003). This refers not only to the large numbers of non-English-speaking Internet users who have developed their own jargons and usages, but also to those who do not participate fully in the subcultural linguistic practices of Netspeak. The degree to which individual users employ the innovative vocabulary of Netspeak and other highly marked in-group writing practices (e.g., consonant writing, emoticons, and abbreviations such as LOL) depends not only on the degree of their integration into the virtual speech community (Paolillo, 1999), but also on the genre (e.g., business e-mail vs. IRC) and the identity they wish to project within a particular communicative context (cf. also Crystal, 2001 on differences in language use across various 'Internet situations').

Semantics-Pragmatics Boundary

A Bezuidenhout, University of South Carolina,

The Philosophical Debate

Texts in the philosophy of language frequently cite the tripartite distinction between syntax, semantics, and pragmatics made by Morris (1938). According to Morris, syntax is concerned with the structural properties of signs (i.e., with word-word relations), semantics with the relations between signs and the things they signify (i.e., with word-world relations), and pragmatics with the uses of signs by speakers and hearers to perform communicative acts (i.e., with word-user relations).

Philosophers generally follow Frege in rejecting any form of mentalist semantics. They think of languages as “abstract semantic systems whereby symbols are associated with aspects of the world” (Lewis, 1972: 170). There is a potential infinity of both syntactically well-formed (grammatical) and semantically well-formed (meaningful) sentences in any language, and it is the job of semantics to identify rules that generate this potential infinity. On the other hand, since we are interested in the semantics of **natural** languages, these rules must be ones that are learnable by humans with finite minds. Semanticists are interested in what a competent speaker knows when she knows a language (i.e., her syntactic and semantic competence). Hence they assume that what a speaker knows is a **finite** set of rules that can compositionally generate the potential infinity of syntactically well-formed sentences and that can deliver a **semantic interpretation** for every meaningful sentence of the language.

Philosophers generally assume that there is a sharp division between syntax/semantics and pragmatics. While semantics studies the rules that a competent speaker knows when she knows the meanings of sentences, pragmatics studies how sentences are used in conversational contexts to communicate a speaker’s messages. Pragmatics is thus concerned with linguistic **performance** rather than competence. It is **by** using sentences with certain syntactic and semantic properties that speakers succeed in communicating certain things. So, the central question of pragmatics is how we succeed in our communicative tasks.

Many philosophers are convinced that Grice (1975, 1989) made an important start in answering this question by articulating his Cooperative Principle and maxims of conversation. Grice sees conversations as rational cooperative activities where hearers use

their linguistic knowledge, together with mutually available nonlinguistic contextual knowledge, to infer what the speaker means to communicate. The principles that guide conversations are analogous to the principles that guide any sort of rational cooperative activity, such as the joint activity of building a house or sailing a ship. Pragmatic principles on this view are not tied essentially to any language mechanism and are certainly not language-specific rules, unlike the syntactic and semantic rules that define a language.

An alternative view, argued for by Prince (1988, 1997), assumes that there are rules of use associating certain linguistic forms with certain functions. Moreover, these rules are language-specific, in the sense that the same pragmatic function could be served in different languages by different forms; so any competent speaker of the language must learn these rules. Knowledge of these rules constitutes the speaker’s pragmatic competence. Hence it is incorrect to put the study of pragmatics on the performance side of the competence/performance divide. Related to Prince’s ideas are those of Kasher (1991), who argues for a modular conception of pragmatics. Just as linguists have postulated a grammar module, so Kasher argues there is a module governing pragmatic processes, with its own proprietary rules and representations. Since it is Grice’s conception of pragmatics that has set the agenda for debate in the philosophy of language, these alternative views will be set aside here.

Gricean pragmatics introduces the idea that it is **by** saying certain things in certain contexts that speakers are able indirectly to communicate (to implicate) certain further things. In working out what a speaker has implicated, a hearer will use his knowledge of the conversational maxims, together with contextually available knowledge, to infer what the speaker communicated. For example, after a terrible ordeal in which a man is rescued from a remote mountainside after a plane crash, a TV reporter interviews him. The reporter asks: ‘Were you ever afraid?’ and the man replies: ‘I felt a twinge or two.’ By his understatement he has implicated that things were pretty bad. The understatement is a violation of Grice’s first Maxim of Quantity, which enjoins speakers to say as much as is required by the purposes of the talk exchange. The hearer, having recognized the violation, but assuming that the speaker is still bound by the Cooperative Principle, will search the context for further information that the speaker might have intended to convey. It is his background knowledge – of human psychology, of the probable consequences of plane wrecks, and of the low probability of survivors being found

in remote, sparsely populated places – that allows the reporter to infer the speaker's intended meaning.

The currently dominant view in philosophy of language is that a theory of meaning for a language specifies the truth-conditions for each of the sentences of a language. It does this by specifying a finite set of rules that compositionally generates these truth-conditions. This truth-conditional approach to semantics has been grafted onto a Gricean view of pragmatics. It is generally accepted that saying and implicating are neatly separated. Saying is tied to sentence meaning and the expression of truth-conditional content. What a speaker says when she utters a sentence (i.e., the locutionary content of her utterance) corresponds to the truth-conditional content of the sentence. (Note that the notion of **saying** is not to be conflated with the notion of **stating**. The former is a locutionary act, namely the act of expressing some content. The latter is an illocutionary act. It is the expressing of some content with a particular illocutionary force.) Implicating is tied to (indirectly or implicitly) communicated content that can be inferred once the hearer has figured out what the speaker has (directly or explicitly) said. Since truth-conditional content is the province of semantics and implicature is the province of pragmatics, the saying/implicating divide goes along with a neat divide between semantics and pragmatics. Consequently, many believe that truth-conditions can be specified in a way that is essentially free from pragmatic considerations.

But there are problems with this Gricean view. One of the first indications of trouble for this view came from some observations by Cohen (1971). Others, such as Carston (1988, 2002), Levinson (1995, 2000) and Recanati (1989, 2004) have used examples similar to Cohen's to challenge the Gricean picture. Consider examples such as the following:

- (1) Mary fell pregnant and she got married.
- (2) Mary got married and she fell pregnant.

Grice would say that (1) and (2) have the same truth-conditional content, but that they implicate different things. (1) implicates (in a generalized way) that the pregnancy occurred before the marriage, whereas (2) implicates the opposite. (1) also implicates that the reason for Mary's marriage was her pregnancy. However consider examples such as the following:

- (3) If Mary fell pregnant and she got married, her grandma will be shocked.
- (4) If Mary got married and she fell pregnant, her grandma will be shocked.

According to Grice, the antecedents of the two conditionals have the same truth-conditional content. Therefore, (3) and (4) should themselves have the

same truth-conditional content, yet intuitively they do not. (3) could be true while (4) is false. It looks as though the implicated content of (1) and (2) has become incorporated into the truth-conditional content of (3) and (4). In other words, (3) and (4) in effect express the following:

- (3') If Mary fell pregnant *and then for that reason* she got married, her grandma will be shocked.
- (4') If Mary got married *and then* she fell pregnant, her grandma will be shocked.

Clearly, (3') and (4') differ in content, so it is not a problem if one is true and the other is false.

These appear to be cases of pragmatic intrusion into truth-conditional content. Such pragmatic intrusion creates a problem for Grice that Levinson (2000) calls 'Grice's Circle.' The trouble is that to figure out what is conversationally implicated, the hearer must first determine what is said (since it is **by** saying such-and-such that a speaker succeeds in implicating something else). However, in figuring out what was said by (3) or (4), it looks as though one must first determine their implicated contents.

Levinson (1995, 2000) argues that pragmatic intrusion is not problematic, since it is limited to the intrusion of **generalized** conversational implicatures (GCIs), and these, he argues, are **default meanings** that will be automatically triggered by the use of certain kinds of expressions. The derivation of GCIs is governed by various heuristic principles. For example, the I-Principle can be summarized in the slogan 'What is simply described is stereotypically and specifically exemplified.' It applies only to 'unmarked, minimal expressions' (Levinson, 1995: 97). It enjoins speakers to minimize what they say when their hearers are able to use contextually accessible information to enrich the informational content of their utterances. Conversely, it enjoins hearers to amplify or enrich the informational content of the speaker's utterance up to the point that they judge is the speaker's intended meaning. Since 'and' is the sort of minimal, unmarked expression that calls for a stereotypical interpretation, conjunctions such as (1) and (2) will be given an interpretation according to which the events described by the two conjuncts are temporally ordered. The net effect is that (3) and (4) will be understood to express (3') and (4') respectively.

Not everyone would agree that in (3) and (4) we have pragmatic intrusion into truth-conditional content. Cohen (1971) appeals to examples of embedded conjunctions that seem to affect the truth-conditions of the larger sentences in which they are embedded to argue for a **semantic ambiguity** account of 'and.' If the suggestion of temporal ordering associated with (1) affects the truth-conditions of (3), Cohen

concludes that this feature must be part of the semantically encoded meaning of 'and.' Since relations other than temporal ordering can be suggested by a conjunction, this view is committed to a multiple ambiguity account of 'and.' In addition to conjunctions such as (1) and (2), consider examples such as:

- (5) It is summer in Europe and winter in Australia.
- (6) The fan turned on and {as a result} a cool breeze blew through the room.
- (7) Peter took a shower and {while in the shower} he practiced his singing.

In some cases, as in example (5), 'and' expresses simple truth-functional 'and,' and the conjuncts can be reversed without changing the meaning. In others, such as (6), it expresses a causal relation 'and as a result,' or, as in (7), a temporal containment relation 'and while.' In these last two cases, the relations are asymmetric, and reversing the conjuncts changes the meaning. For instance, reversing (6) suggests a different causal scenario, where the breeze somehow turns on the fan. Examples could be multiplied, and for each case where a different relation is suggested, Cohen would have to posit yet another meaning for 'and.'

Carston (1988) and Recanati (1989) argue against positing a semantic ambiguity for 'and,' maintaining instead that the contents represented between brackets in the above examples are **pragmatically determined aspects of what is said**. (See entry on **Pragmatic Determinants of What Is Said**.) Rather than being semantically ambiguous, 'and' is **semantically underspecified**. It will be pragmatically enriched in different ways, depending on the assumptions that are operative in the conversational context.

Carston and Recanati agree with Levinson that there is pragmatic intrusion. However, they point to embedded contexts, like the conditionals (3) and (4), to argue that the pragmatic content associated with (1) and (2) belongs to what is said, rather than being conversationally implicated. (Carston (2002) prefers to use Sperber and Wilson's (1986) technical term 'explicature' instead of the term 'what is said,' since the latter has a commonsense usage that interferes with attempts at terminological regimentation.) If the pragmatic content of a simple sentence has an effect on the truth-conditional content of the compound sentences in which it is embedded, then that pragmatic content is part of what is said by the simple sentence, not something that is merely implicated. Recanati calls this the Scope Test.

Other tests have been proposed for determining whether some pragmatically determined content is part of what is said. Recanati (1989) proposes his Availability Principle, according to which any content

that intuitively seems to affect truth-conditions should be regarded as a part of what is said. Carston (1988) proposes her Functional Independence Principle, which requires both explicatures and implicatures to occupy independent roles in inferential interactions with other assumptions. Take example (8) discussed below. The simple encoded content that Mary engaged in an act of swallowing is not functionally independent of the enriched content that Mary swallowed a bug. The latter entails the former, and it is from the latter that further contextual effects can be derived. This suggests that it is the enriched content that corresponds to what is said, not the more minimal encoded content, which has no autonomous role to play.

Explicatures are pragmatic developments of semantically encoded content and can be either **enrichments** or **loosenings** of encoded content. Carston argues that the processes involved in the recovery of explicatures are inferential processes and, hence, no different from the sorts of inferential processes involved in the derivation of conversational implicatures. What distinguish explicatures from implicatures are not the sorts of processes involved in their derivation but the starting points of these inferential processes. Derivations of explicatures begin with the semantically underspecified representations of logical form (LF) that are the output of processes of grammatical decoding. Implicatures, on the other hand, as Grice insisted, are contextual implications that follow from contexts including assumptions about what was said (i.e., including explicatures). This is **not** a commitment to the claim that explicatures are processed before implicatures. In fact, Carston thinks that the processing of explicatures and implicatures happens in parallel, and that the overall interpretation of a speaker's utterance is something arrived at via a process of mutual adjustment.

Recanati, on the other hand, distinguishes local from global pragmatic processes. The sorts of processes involved in the derivation of pragmatic determinants of what is said are of the local sort and are noninferential. For instance, such local processes might involve spreading activation within an associative conceptual network, or the accessing of stereotypical information from conceptual frames or scripts. Such processing happens at a subconscious level, and only the output of such processes is consciously available. In contrast, global pragmatic processes are inferential processes of the sort that Grice claimed are involved in the derivation of conversational implicatures. Such inferential processing is in principle consciously available, in the sense that language users can become aware not just of the conclusions of such reasoning but also of the inputs to such reasoning,

as well as to the (putative) fact that premises and conclusions are inferentially connected.

Bach (1994) provides yet another perspective on these matters. Bach wishes to maintain a more minimalist conception of semantics and of what is said. Yet he acknowledges that there are pragmatically determined contents that are not Gricean implicatures. He introduces a third category of contents, intermediate between what is said and what is implicated, that he labels 'implicatures.' He regards these as contents that are implicit in what is said and that require pragmatic processes of either **completion** or **expansion** to be made explicit. Consider the following, where the content in brackets is supplied from contextually available information:

- (8) Mary swallowed {the bug that flew into her mouth}.
- (9) Mary invited everyone {in her department} to her wedding.

The sentence 'Mary swallowed' is syntactically and semantically complete. (Compare it to 'Mary ate,' which is syntactically but not semantically complete, since 'eat' is a two-place relation. Or to 'Mary devoured,' which is neither syntactically nor semantically complete, since 'to devour' subcategorizes for an obligatory second NP, and 'devour' has two semantic arguments). Bach regards (8) as an example of **conceptual** incompleteness, and hence a pragmatic process of completion must operate, resulting in the derivation of the implicature that Mary swallowed the bug that flew into her mouth.

On the other hand, 'Mary invited everyone to her wedding' expresses a complete proposition. Bach calls this a **minimal proposition**, since the domain of the quantifier is not restricted in any way (beyond the restriction to persons that is encoded by 'one' in 'everyone'). However, this minimal proposition is not the one that the speaker intends to communicate. A pragmatic process of expansion is required, yielding the implicature that Mary invited everyone in her department to her wedding. Bach calls examples such as (9) cases of **sentence nonliterality**. No expression in the sentence is used nonliterally, yet the minimal proposition expressed by the sentence is not what the speaker intends to convey.

Bach denies that there are pragmatically determined aspects of what is said. What is said for Bach is a more minimal notion, which is tied to explicitly encoded semantic content. Bach in effect accepts what Carston (1988) calls the Linguistic Direction Principle. The only contextually determined content that belongs to what is said by the utterance of a sentence is content that corresponds to some element that is syntactically realized in that sentence. Thus the

contextual values of the indexicals in 'She is swallowing now' will be part of what is said by an utterance of this sentence, but the implicit content that specifies what was swallowed (if anything) will not be a part of what is said, since that content corresponds to no element in the sentence. Bach's minimalism requires him to admit that on some occasions what a speaker says does not correspond to a complete proposition. Such is the case in example (8) above. In such cases Bach argues that what is said corresponds to a 'propositional radical,' a gappy object whose missing conceptual elements must be supplied by the context.

Each of the authors discussed above posits a different view of the boundary between semantics and pragmatics. According to Grice, sentence meaning, truth-conditional content, and what is said are all aligned and fall on the side of semantics, whereas implicatures fall on the side of pragmatics. Cohen basically preserves Grice's dichotomy. Cases that may seem to be pragmatic intrusions into truth-conditional content are instead incorporated into semantics. If there is a challenge to Grice it is simply that some phenomena that Grice would label as conversational implicatures are reanalyzed by Cohen as part of semantically encoded content, so that the domain of pragmatics shrinks.

Subsequent views can all in one way or another be seen to challenge Grice's neat dichotomy. Bach remains the most faithful to Grice, since on the whole he preserves the alignment of sentence meaning, truth-conditional content, and what is said on the side of semantics. Truth-conditional content may sometimes come apart from what is said, in those cases in which what is said is conceptually incomplete and hence does not correspond to a complete, truth-evaluable proposition. But when we have truth-conditional content, it is something that is delivered purely by semantics. However, Bach argues that Grice's view of what lies on the side of pragmatics is inadequate. The phenomena of semantic underspecification and sentence nonliterality require us to recognize a category of pragmatic content intermediate between what is said and what is implicated – the category of implicatures.

Levinson's (1995, 2000) views are also quite close to Grice's. He accepts that sentence meaning and what is said line up, and that these are semantic phenomena. However, he allows that there can be pragmatic intrusion into truth-conditional content, so this notion is not a purely semantic notion. On the other hand, Levinson's conception of pragmatics is conservative. He does not challenge the adequacy of the Gricean conception of pragmatics as the domain of conversational implicatures. He does, however, develop Grice's notion of a generalized

conversational implicature (GCI) to a substantial degree. GCIs are said to be default meanings, which belong to a third level of meaning that Levinson calls utterance-level meaning, different from either sentence meaning or speaker meaning. It is only GCIs that are involved in pragmatic intrusion.

Carston's and Recanati's challenges to Grice are more radical. For them, the only purely semantic notion is sentence or expression meaning. What is said (which is equated with truth-conditional content) falls on the side of pragmatics, since there is pragmatic intrusion into truth-conditional content. (Remember, Carston prefers the term 'explicature.') Carston (2002) suggests that we make a distinction between lexical and truth-conditional semantics. Lexical semantics studies those aspects of meaning that have some sort of syntactic reflex in the language and hence that are a part of the mental lexicon. The lexicon is a store of words in long-term memory. An entry in the mental lexicon is in effect a rule correlating the phonological, syntactic, and semantic information associated with a word. Lexical semantics on this conception is a mentalist enterprise. We can continue to talk of truth-conditional semantics, so long as we realize that the project is very different from the traditional one. Truth-conditions are not assigned directly to the sentences of a language, since sentences by themselves do not have truth-conditions. It is only sentences as used by speakers in particular conversational contexts that have truth-conditions. For a defense of a similar claim, see Stainton (2000).

Moreover, both Carston and Recanati reject Gricean pragmatics as inadequate, since for them pragmatics is not confined to the study of conversational implicatures. Recanati's rejection of Gricean pragmatics may be the most thoroughgoing, since for him, the pragmatic processes involved in the recovery of what is said are not even of the same type as the global pragmatic processes involved in the recovery of implicatures. They are noninferential processes.

Many other voices have been added to this debate. For example, Stainton (1995) argues for the view that semantic underspecification and pragmatic intrusion is rife. He points to the fact that many utterances are of sentence fragments, rather than of complete sentences. Consider:

(10) Top shelf.

Suppose Mary is making herself a sandwich and is rooting around in the kitchen cupboard looking for jam to spread on her toast, and that this is mutually manifest to Mary and her husband Peter. Peter could utter sentence fragment (10), meaning to convey the proposition that the jam that Mary is looking for is on

the top shelf of the cupboard she is searching in. Stainton argues that cases such as these are not to be treated as cases of ellipsis. The missing content in (10) need not correspond to any well-defined syntactic element, as happens in standard cases of syntactic ellipsis, such as the VP-ellipsis in 'Mary donated blood and so did Peter.' (Ellipsis is a very vexed subject. Whether it is something that can be handled in the syntax is not at all clear. See Jackendoff, 1997: 75–78, for a discussion of some problematic cases.) We should accept that language understanding is able to proceed on the basis of fragmentary clues from semantically decoded content. A large burden is placed on the inferential capacities of hearers, who must elaborate these clues on the basis of contextually available information.

Stanley (2002) argues for a diametrically opposed view. According to Stanley, there is much more syntactic and semantic structure than meets the eye, and many of the alleged cases of semantic underdetermination calling for pragmatic enrichment can be re-analyzed as cases where some hidden element in the underlying sentential structure is directing the process of content retrieval. In other words, we preserve the idea of the linguistic direction of content, although the elements doing the directing are often hidden elements (ones that are not phonetically realized, although they are a part of underlying logical form).

Stanley's views have been especially influential in accounting for cases of quantifier domain restriction, such as (9) above or (11) below:

(11) Every child has been vaccinated against polio.

(12) In every country, every child has been vaccinated against polio.

It is possible to use (11) in an appropriate context to convey the proposition that every child **in the United States** has been vaccinated against polio. Stanley's view is that there must be a hidden free variable in (11) whose value is specified in that context as the United States. This variable is present in the underlying logical form of (11) but is not phonetically realized. (Strictly speaking, what is implicit is a free **function** variable, and what must be specified in context is both the function and the values of the arguments of this function. In (11) the function is something like 'resident-in(x).') The evidence that there is a hidden free variable in (11) is that this variable can sometimes be bound by a quantifier. For example, when (11) is embedded in a sentence with a quantifier that has wide scope over the embedded quantifier, as is the case in (12), what is said is that in every country *x*, every child *in x* has been vaccinated. For more detailed arguments, both pro and con, see Stanley and Szabó (2000), Bach (2000)

and Neale (2000). This hidden indexical view has consequences for the quantificational analysis of definite descriptions and has led to some controversy as to the correct analysis of so-called incomplete descriptions. See the chapters in Part I of Reimer & Bezuidenhout (2004).

The Mentalist Picture of the Semantics-Pragmatics Boundary

It was noted above that many philosophers follow Frege in rejecting mentalist semantics. Many linguists on the other hand embrace mentalism, and in fact regard it as the only sensible perspective from which to study language. See Chomsky (2000), Jackendoff (1997, 2002). From the point of view of mentalism, the dispute about the semantics-pragmatics boundary is not one about how to delineate the notions of explicature, implicature, implicature, etc. Rather, it is concerned with the question as to how semantic and pragmatic knowledge are represented and organized in the human mind/brain and how this information is combined in the course of on-line production and comprehension of language. Several of the authors discussed above straddle the divide between philosophy and linguistics. Carston, for instance, works in the mentalist tradition. She is concerned to offer a mentalist theory of language **performance**. (So the suggestion made at the outset that semantics is concerned with competence and pragmatics with performance is one that Carston would reject.) On the other hand, although she is interested in articulating a cognitive theory of performance, she has also been an active contributor to the philosophical debate about how to delineate what is said from what is conversationally implied.

Within the mentalist framework, the dominant picture of the semantics-pragmatics interface has been that it is the interface between the language system proper and what Chomsky (1995) calls the conceptual-intentional system. From the comprehension perspective, this interface is where the output from the hearer's language system, namely a representation of the logical form (LF) of the speaker's utterance, is interpreted by processing it in the context of currently active pragmatic information, including information about the speaker's likely communicative intentions. From the production perspective, this interface is where the process of giving expression to a speaker's communicative intentions is initiated. Appropriate lexical-conceptual entries in the speaker's mental lexicon are accessed, thus initiating a process that will ultimately result in the output of an appropriate phonetic form (PF) at

the interface between the language system and the articulatory system.

Jackendoff (1997, 2002) challenges this Chomskyan view while remaining within the mentalist camp. He argues that the language system has a tripartite parallel architecture. There are three independent generative systems or modules, the phonological system, the syntactic system, and the conceptual system. Each contains its own compositional rules and proprietary set of representations, of, respectively, phonological structure (PS), syntactic structure (SS), and conceptual structure (CS). However, it is necessary for these systems to communicate with one another, and they do this via various interface modules, whose job it is to map representations from one system into the representations of another. There is a PS-SS interface, an SS-CS interface (which Jackendoff calls the syntax-semantics interface), and a PS-CS interface. The lexicon is also an interface module, and the interfaces already mentioned are in effect parts of this larger interface system. The lexicon is a long-term memory store whose entries are triples of the three sorts of structures mentioned, namely of PS, SS, and CS. The lexical entry for expression α , $\langle PS_\alpha, SS_\alpha, CS_\alpha \rangle$, is in essence a correspondence rule mapping representations from the three systems into each other. (Lexical entries may be for words, for phrases, such as idioms, or for expressions below the word level, such as agreement markers.)

What Jackendoff calls the syntax-semantics interface (namely the SS-CS interface) is of relevance to the current discussion, since he justifies his claim that CS is the level of semantics, and that it is a level separate from syntax, by appeal to phenomena of the sort that Carston, Recanati, and others appeal to in arguing for pragmatic intrusion into what is said (i.e., into the proposition expressed by an utterance). Jackendoff (1997) argues for what he calls enriched semantic composition. At the level of CS, the compositional principles that form propositions (or thoughts) are sensitive to information that comes from the pragmatic context. But not all this conceptual structure is reflected in the corresponding syntactic structures. Consider the following:

- (13) Peter kept crossing the street.
- (14) Mary finished the book.
- (15) The ham sandwich wants his check.

(13) illustrates the process of aspectual coercion, (14) of co-composition, and (15) of pragmatic transfer. See Pustejovsky (1995) for an account of the first two processes and Nunberg (1979) for an account of the third.

A single act of crossing the street is not a repetitive and (potentially) open-ended action like clapping one's hands or bouncing or spinning a ball. But 'kept' requires such repetitiveness and/or open-endedness. Thus, in the case of (13), 'kept' coerces an interpretation of 'crossing the street' according to which there is either a repeated or an extended action. That is, either we understand Peter to have crossed the street multiple times, perhaps in his effort to lose the detective tailing him. Alternatively, we zoom in on Peter's action of crossing the street and see it as one whose end point is still in Peter's future. Perhaps the street is a very broad one, with a median strip, where Peter pauses briefly before continuing with his crossing.

In the case of (14), finishing is something that can be predicated of an event, but 'the book' refers to an object, not an event. Pustejovsky (1995) argues that the lexical-conceptual entry for 'book' contains information about the typical features of books, namely that they have authors, are read by readers, etc. This conceptual information, presumably along with other contextual information, can be used to arrive at an enriched interpretation of (14) according to which Mary finished reading (or writing, or binding, or illustrating, etc.) the book. In the case of (15), contextual knowledge about restaurants and what goes on in them is used to arrive at an interpretation according to which the ham sandwich orderer wants his check.

In all these cases Jackendoff argues that there is more conceptual (semantic) structure than is represented syntactically. Some will be inclined to argue that there must be covert syntactic structure to match the semantic structure – structure that is there but is not phonetically realized. But Jackendoff argues that this is a mistake. Those who argue for covert structure are in the grip of an assumption that he calls syntactocentrism, namely the view that the only source of compositional structure is syntax. This is an assumption he attributes to Chomsky, since it is built into all the theories of the organization of the language system that Chomsky has proposed, from the Standard Theory of the 1960s, through the extended and revised versions of the Standard Theory in the 1970s, to the Government and Binding (GB) approach of the early 1980s and the minimalist approach of the 1990s. But Jackendoff's account of the tripartite parallel architecture of the language system rejects this assumption.

Moreover, Jackendoff goes further and argues that it is a mistake to talk of any semantic structure being directly encoded in the syntax, as Chomsky seems to suggest when he introduces the level of logical form (LF) and talks of it as the level in syntax that directly represents meaning (Chomsky, 1986: 68). It is

unnecessary and perhaps even incoherent to talk in this way. First, it is unnecessary, since the correspondence rules belonging to the syntax-semantics interface (the SS-CS interface) will do the work of correlating syntactic and semantic structures. Note also that the correspondence doesn't have to be perfect. There may be only a partial homology between these two systems. If the communicative system as a whole works in such a way that semantic structure is recoverable from readily available contextual knowledge, then the fact that some of this structure is invisible to the syntactic system is no bad thing.

Second, talk of semantic structure being encoded in syntax may be incoherent if that is allowed to mean that semantic distinctions are directly represented in the syntactic system. The syntactic system is a module whose internal operations are defined over representations in its own proprietary code. So the syntactic system knows about nouns and verbs, case markings, active and passive constructions, WH-movement, etc., not about objects and events, predicate-argument structure, the telic/atelic distinction, thematic roles, etc. Thus it could not represent the sort of pragmatic knowledge needed to interpret examples such as (13)–(15).

As already mentioned, Carston accepts Chomsky's picture, including the assumption of syntactocentrism. She holds that the output from the language system is a representation of LF, which includes those semantic features that are directly syntactically encoded. Earlier we saw her acceptance of the idea that lexical semantics is the study of such encoded aspects of meaning. So, for her, the SS-CS interface would be better called the semantics-pragmatics interface, not the syntax-semantics interface. This makes it seem that her views are very far from those of Jackendoff. Yet Carston's notion of pragmatic enrichment and Jackendoff's notion of enriched composition are very similar.

Jackendoff (2002: 273) does briefly allude to what he might call the semantics-pragmatics interface. It turns out to be an interface level between two sub-levels **within** the conceptual system. It is the level that integrates thoughts that are conveyed by means of language with one's previous knowledge, including knowledge of the communicative context and the speaker's intentions. Such integration may lead one to inferentially derive further thoughts (i.e., Gricean implicatures). In other words, Jackendoff's conception is basically the Gricean conception that is rejected by Carston, since it confines pragmatics to the derivation of implicatures, whereas Carston thinks pragmatic processes are also involved in the enrichment of lexical concepts (encoded meanings) to

arrive at ad hoc concepts (contextualized meanings). Of course, Jackendoff can use terminology in the way he pleases. However, to make it clearer that his views are in fact very close to those of Carston, it might be more appropriate to relabel Jackendoff's SS-CS interface the syntax-pragmatics interface.

This does of course still leave some disagreements unsettled. In particular, it leaves unsettled the issue of syntactocentricism and the debate as to whether there is a specifically linguistic part of semantics, separate from nonlinguistic knowledge, thought, and contextualized meaning. (See Jackendoff, 2002: 281–293, for reasons to deny that there is any such level of semantics.)

Shared Knowledge

A Capone, Barcellona, Italy

© 2006 Elsevier Ltd. All rights reserved.

What is it to know a proposition? A person A knows that proposition p if and only if (iff):

- A believes that p;
- A is justified in believing that p;
- p is true.

So there are three clauses that must be satisfied for a state of knowledge to be correctly ascribed to A. To explicate each of the three clauses would be a Herculean task, for the first clause would require a theory of propositional attitudes, the second clause would require a theory on what counts as appropriate justification for a belief, and the third clause requires a theory of truth. We accept, without making a real effort to justify it, the idea that for A to believe a proposition p is to be in a mental state that is likely to influence A's conduct; we also accept that a person has appropriate justification for a belief if he or she has canonical evidence guiding him or her toward ascertaining the truth; we accept that a proposition p is true if the world conforms to some mental state p or some fact p or if p is a proposition accepted by convention or stipulation within a certain society.

Having defined knowledge in this way, we are able to refute the skeptics and in particular to counter the skeptics' attacks on shared knowledge. From the fact that knowledge can be revised, we should not deduce that there is no knowledge or no shared knowledge.

What is shared knowledge? An intuitive definition could be one like the following: two persons, A and B, share knowledge of a proposition p iff they both know that p and if they both know that the other knows that p and that B knows that A knows that B knows that p and A knows that B knows that A knows that p. In other words, shared knowledge is not just knowledge on A's part that the other person, B, knows a proposition p that A also knows, but also knowledge that the other person knows that A knows that p. The definition does not necessarily generate

infinite recursion; a regress of the second or third order may suffice for the purpose of practical understanding. In any case, even infinite recursion can be finitely represented, albeit not at the conscious level (a simple mathematical example is the case of recursion in 3.3 periodical).

How can shared knowledge be obtained? Shared knowledge can be constructed through shared perceptual stimuli or through publicly vocalized utterances. Suppose you and I stand in front of the Statue of Liberty in New York City: both of us see the imposing statue, and there is little doubt that it does not escape our attention; we are confronted with something that we cannot but see. Shared knowledge can also be constructed linguistically, by referring to an authority, or in general, to human linguistic productions.

Of course, shared knowledge is a testable assumption; one assumes it to be present unless there are overwhelming reasons for doubting that things are as they are assumed to be. It is possible, albeit unlikely, that you are momentarily blinded, that I do not realize that fact, and that I erroneously assume that you know that the Statue of Liberty is there in front of you; however, this assumption can easily be tested by analyzing your reply (or absence of reply) to my casual remark, as when I say "That statue is impressive"; in the absence of an appropriate reply, I realize that the presumption of shared knowledge was not justified. But this is not the way we standardly proceed. We just assume that salient visual (and other) stimuli are part of our shared knowledge, and we do not put this assumption to the test.

Sibata, Takesi

Y Nagashima, Gakushuin University, Tokyo, Japan

© 2006 Elsevier Ltd. All rights reserved.

Takesi Sibata was born in Nagoya, Japan on July 14, 1918. He graduated from the University of Tokyo with an M.A. in 1942 and received his D.Litt. in 1969 from the same university. He was a professor at Tokyo University of Foreign Studies from 1964 to 1968 and then became professor at his alma mater in 1968, where he was chairman of the Department of Linguistics from 1969 to 1978 and remained there until his retirement in 1979. He received the title of Professor Emeritus of the University of Tokyo in 1987.

His major fields include Turkish, linguistic geography, sociolinguistics, onomastics, and Japanese lexicology. He worked for the National Institute for Japanese Language Research from 1949 to 1964. His major work there was the preparation of the massive *Nihon Gengo Chizu (Japanese Linguistic Atlas)*, which was published in six volumes from 1966 to 1975. Parallel with this work, he carried out other intensive fieldwork on linguistic geography in Itoigawa area, Niigata Prefecture, with several collaborators. The unique feature of the survey was a microscopic survey of every inhabitant in the area. Through the analysis of the survey, he developed an original method of linguistic geography, the outline of which can be seen in Sibata (1969). The publication of the whole work was completed in the form of Sibata (1988–1995).

In the field of sociolinguistics, he put forward a new point of view from which to survey people's verbal behavior in every aspect of everyday life:

when and how people speak, listen, write, read, and keep silent. This whole complex of activities is called in Japanese *gengo seikatsu*, which literally means 'verbal life'.

Sibata has also contributed greatly to the development of Japanese lexicology and lexicography. He produced three volumes on the semantic analysis of basic Japanese words with other colleagues. He is a co-editor of several Japanese dictionaries, and was especially responsible for the description of word accents and the meaning of loanwords. Since 1966, he has been a member of the Committee for Japanese for Broadcasting at Nihon Hoso Kyokai (Japanese Broadcasting Corporation) and a member of the government committee for Japanese language policy. He also served as a member of the Japan Academic Association from 1988 to 1994.

Sign Language: Overview

W Sandler, University of Haifa, Haifa, Israel

© 2006 Elsevier Ltd. All rights reserved.

In many ways, sign languages are like spoken languages: They are natural languages that arise spontaneously wherever there is a community of communicators; they effectively fulfill all the social and mental functions of spoken languages; and they are acquired without instruction by children, given normal exposure and interaction. These characteristics have led many linguists to expect sign languages

to be similar to spoken languages in significant ways. However, sign languages are different too: As manual–visual languages, sign languages exploit a completely different physical medium from the vocal–auditory system of spoken languages. These two dramatically different physical modalities are also likely to have an effect on the structure of the languages through which they are transmitted.

It is of special interest, then, to compare natural languages in the two modalities. Where the two systems converge, universal linguistic properties are revealed. Where they diverge, the physical medium

of transmission is implicated, and its contribution to the form of language in both modalities is illuminated. Neither can be seen quite so clearly if linguists restrict their study to spoken language alone (or to sign language alone). For this and other related reasons, it is often remarked that sign languages provide us with a natural laboratory for studying the basic characteristics of all human language.

Once the existence of natural language in a second modality is acknowledged, questions such as the following arise: How are such languages born? Are the central linguistic properties of sign languages parallel to those of spoken languages? Is sign language acquired by children in the same stages and time frame as spoken language? Are the same areas of the brain responsible for language in both modalities? What role does modality play in structuring language? In other words, within the architecture of human cognition, do we find the structure of one language ‘faculty’ or two? Although there is no conclusive answer to this deceptively simple question, an impressive body of research has greatly expanded our understanding of the issues underlying it.

How Do Sign Languages ‘Happen’?

Evolution made language possible scores of millennia ago, and there is no human community without it. What sign language teaches us is that humans have a natural propensity for language in two different modalities: vocal–auditory and manual–visual. Since the human ability to use language is so old, and since speech is the predominant medium for its transmission, it seems that spoken languages are either also very old or descended from other languages with a long history. However, sign languages do not have the same histories as spoken languages because special conditions are required for them to arise and persevere, and for this reason they can offer unique insight into essential features of human language.

The first lesson sign language teaches us is that, given a community of humans, language inevitably emerges. Although we have no direct evidence of the emergence of any spoken language, we can get much closer to the origin of a sign language and, in rare instances, even watch it come into being.

Wherever deaf people have an opportunity to gather and interact regularly, a sign language is born. Typically, deaf people make up a very small percentage of the population (approximately 0.23% in the United States, according to the National Center for Health Statistics, 1994) so that in any given local social group, there may be no deaf people at all or very few of them. The most common setting in which a deaf community can form, then, is a school for deaf

children. Such schools only began to be established approximately 200 years ago in Europe and North America. On the basis of this historical information and some reported earlier observations of groups of people using sign language, it is assumed that the oldest extant sign languages do not date back farther than approximately 300 years (Woll *et al.*, 2001). Currently, linguists have the rare opportunity to observe the emergence and development of a sign language from the beginning in a school established in Nicaragua only approximately 25 years ago – an opportunity that is yielding very interesting results.

Graduates of such schools sometimes choose to concentrate in certain urban areas, and wider communities arise and grow, creating their own social networks, institutions, and art forms, such as visual poetry (Padden and Humphries, 2005; Sandler and Lillo-Martin, 2005; Sutton-Spence and Woll, 1999). Deaf society is highly developed in some places, and the term ‘Deaf’ with a capital D has come to refer to members of a minority community with its own language and culture rather than to people with an auditory deficit.

It is not only the genesis of a sign language that is special; the way in which it is passed down from generation to generation is unusual as well. Typically, fewer than 10% of deaf children acquire sign language from deaf parents, and of those deaf parents, only a small percentage are native signers. The other 90+% of deaf children have hearing parents and may only be exposed to a full sign language model when they go to school. These social conditions taken together with certain structural properties of sign languages have prompted some linguists to compare them to spoken creoles (Fischer, 1978).

Another way in which a deaf social group and concomitant sign language can form is through the propagation of a genetic trait within a small village or town through consanguineous marriage, resulting in a proportionately high incidence of deafness and the spread of the sign language among both deaf and hearing people. Potentially, this kind of situation can allow us to observe the genesis and development of a language in a natural community setting. Although the existence of such communities has been reported occasionally (see Groce, 1985), no comprehensive linguistic description of a language arising in such a community has been provided.

These, then, are the ways in which sign languages happen. The existence of many sign languages throughout the world – the number 103 found in the Ethnologue database is probably an underestimate – confirms the claim that the emergence of a highly structured communication system among humans is

inevitable. If the oral–aural channel is unavailable, language springs forth in the manual–visual modality.

Not only does such a system emerge in the absence of audition, but its kernels can be also observed even in the absence of both a community and a language model. Deaf children who live in hearing households in which only oral language is used, who have not yet experienced speech training, and thus have no accessible language model, devise their own systematic means of communication called home sign, studied in exquisite detail by Goldin-Meadow and colleagues (Goldin-Meadow, 2003). The gesture talk of these children contains the unmistakable imprint of a real linguistic system, and as such it offers a unique display of the fundamental human genius for language.

At the same time, the form and content of home sign are rudimentary and do not approach the richness and complexity of a language used by a community, spoken or signed. This confronts us with another important piece of information: Language as we know it is a social phenomenon. Although each brain possesses the potential for language, it takes more than one brain to create a complex linguistic system.

The Linguistic Structure of Sign Language

Hearing people use gesture, pantomime, and facial expression to augment spoken language. Naturally, the ingredients of these forms of expression are available to sign languages too. The apparent familiarity of the raw material that contributes to the formation of sign languages has led many a naïve observer to the mistaken assumption that sign languages are actually simple gesture systems. However, instead of forming an idiosyncratic, ancillary system like the one that accompanies speech, these basic ingredients contribute to a primary linguistic system in the creation of a sign language, a system with many of the same properties found in spoken languages. In fact, linguistic research has demonstrated that there are universal organizing principles that transcend the physical modality, subsuming spoken and signed languages alike.

The Phonology of Sign Language

William Stokoe (1960) demonstrated that the signs of American Sign Language (ASL) are not gestures: They are not holistic icons. Instead, Stokoe showed that they are composed of a finite list of contrastive meaningless units like the phonemes of spoken languages. These units combine in constrained ways to create the words of the language. Although there are some differences among different sign languages in their phonological inventories and constraints, there are many common properties, and the generalizations

presented here hold across sign languages, unless otherwise indicated.

Stokoe established three major phonological categories: hand shape, location, and movement. Each specification within each of the three major categories was treated as a phoneme in Stokoe's work. Later researchers accepted these categories but proposed that the specifications within each category function not as phonemes but as phonological features. The ASL signs SICK and TOUCH, illustrated in **Figure 1**, have the same hand shape and the same straight movement. They are distinguished by location only: The location for SICK is the head, whereas the location for TOUCH is the nondominant hand. Minimal pairs such as this one, created by differences in one feature only, exist for the features of hand shape and movement as well. Although the origins of these and other (but certainly not all) signs may have been holistic gestures, they have evolved into words in which each formational element is contrastive but meaningless in itself.

Two other defining properties of phonological systems exist in sign languages as well: constraints on the combination of phonological elements and rules that systematically alter their form. One phonological constraint on the form of a (monomorphemic) sign concerns the set of two-handed signs. If both hands are involved, and if both hands also move in producing the sign (unlike TOUCH, in which only one hand moves), then the two hands must have the same hand shape and the same (or mirror) location and movement (Battison, 1978). An example is DROP, shown in **Figure 2B**: Both hands move, and they are identical in all other respects as well. The second defining property, changes in the underlying phonological form of a sign, is exemplified by hand shape assimilation in compounds. In one lexicalized version of the ASL compound, MIND + DROP = FAINT, the  hand shape of the first member, MIND, undergoes total assimilation to the  hand shape of the second member, DROP, as shown in **Figure 2**.

Figure 1 ASL minimal pair distinguished by a location feature. (A) SICK and (B) TOUCH.

Figure 2 Hand configuration assimilation in the ASL compound. (A) MIND + (B) DROP = (C) FAINT.

Figure 3 The canonical form of a sign. From Sandler (1989).

Stokoe believed that hand shapes, locations, and movements cooccur simultaneously in signs, an internal organization that differs from the sequentiality of consonants and vowels in spoken language. Liddell (1984) took exception to that view, showing that there is phonologically significant sequentiality in this structure. Sandler (1989) further refined that position, arguing that the locations (L) and movement (M) within a sign are sequentially ordered, whereas the hand configuration (HC) is autosegmentally associated to these elements – typically, one hand configuration (i.e., one hand shape with its orientation) to a sign, as shown in the representation in Figure 3. The first location of the sign TOUCH in Figure 1B, for example, is a short distance above the nondominant hand, the movement is a straight path, and the second location is in contact with the nondominant hand. The hand shape of the whole sign is ʔ.

Under assimilation, as in Figure 2, the HC of the second member of the compound spreads regressively to the first member in a way that is temporally autonomous with respect to the Ls and Ms, manifesting the autosegmental property of stability (Goldsmith, 1979). The sequential structure of signs is still a good deal more limited than that of words in most spoken languages, however, usually conforming to this canonical LML form even when the signs are morphologically complex (Sandler, 1993).

Morphology

All established sign languages studied to date, like the overwhelming majority of spoken languages, have complex morphology. First, as shown in Figure 2, compounding is very common. In addition, some sign languages have a limited number of sequential

affixes. For example, Israeli Sign Language (ISL) has a derivational negative suffix, similar in meaning to English *-less*, that was grammaticalized from a free word glossed NOT-EXIST. This suffix has two allomorphs, depending on the phonological form of the base, illustrated in Figure 4. If the base is two-handed, so is the suffix, whereas one-handed bases trigger the one-handed allomorph of the suffix.

Sign languages typically have a good deal of complex morphology, but most of it is not sequential like the examples in Figures 3 and 4. Instead, signs gain morphological complexity by simultaneously incorporating morphological elements (Fischer and Gough, 1978). The prototypical example, first described in detail in ASL (Padden, 1988) but apparently found in all established sign languages, is verb agreement. This inflectional system is prototypical not only because of the simultaneity of structure involved but also because of its use of space as a grammatical organizing property.

The system relies on the establishment of referential loci – points on the body or in space that refer to referents in a discourse – that might be thought of as the scaffolding of the system. In Figure 5, loci for first person and third person are established.

In the class of verbs that undergoes agreement, the agreement markers correspond to referential loci established in the discourse. Through movement of the hand from one locus to the other, the subject is marked on the first location of the verb and the object on the second. Figure 6A shows agreement for the ASL agreeing verb, ASK, where the subject is first person and the object is third person. Figure 6B shows the opposite: third person subject and first person object. The requirement that verb agreement must refer independently to the first and last locations in a sign was one of the motivations for Liddell's (1984) claim that signs have sequential structure.

Although each verb in Figure 6 includes three morphemes, each still conforms to the canonical LML form shown in Figure 3. The agreement markers are

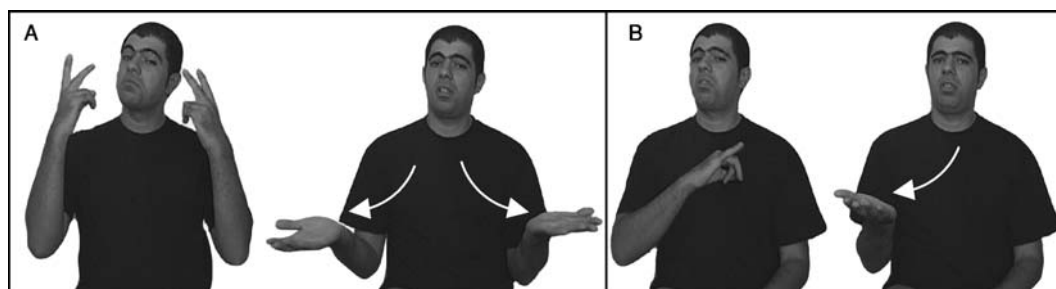

Figure 4 Allomorphs of an ISL suffix. (A) IMPORTANT-NOT-EXIST (without importance). (B) INTERESTING-NOT-EXIST (without interest).

Figure 5 Referential loci. (A) First person. (B) Third person.

encoded without sequential affixation. Sign language verb agreement is a linguistic system, crucially entailing such grammatical concepts as coreference, subject and object, and singular and plural. It is also characterized by sign language-specific properties, such as the restriction of agreement to a particular class of verbs (Padden, 1988), identified mainly on semantic grounds (Meir, 2002).

Another productive inflectional morphological system found across sign languages is temporal and other aspectual marking, in which the duration of Ls and Ms, the shape of the movement path, or both may be altered, and the whole form may be reduplicated, to produce a range of aspects, such as durational, continuative, and iterative (Klima and Bellugi, 1979). This system has templatic characteristics, lending itself to an analysis that assumes CV-like LM templates and nonlinear associations of the kind McCarthy (1981) proposed for Semitic languages (Sandler, 1989, 1990).

Figure 4 demonstrated that some limited sequential affixation exists in sign languages. However, the most common form of sign language words by far, whether simple or complex, is LML (setting aside gemination of Ls and Ms in the aspectual system, which adds duration but not segmental content). In fact, even lexicalized compounds such as the one shown in Figure 2 often reduce to this LML form. If movement (M) corresponds to a syllable nucleus in sign language, as Perlmutter (1992), Brentari (1998), and others have argued, then it appears that monosyllabicity is

Figure 6 Verb agreement. (A) 'I ask him/her.' (B) 's/he asks me.'

ubiquitous in ASL (Coulter, 1982) and in other sign languages as well. In the midst of a morphological system with many familiar linguistic characteristics (e.g., compounding, derivational morphology, inflectional morphology, and allomorphy), we see in the specific preferred monosyllabic form of sign language words a clear modality effect (Sandler and Lillo-Martin, 2005).

No overview of sign language morphology would be complete without a description of the classifier subsystem. This subsystem is quintessentially 'sign language,' exploiting the expressive potential of two hands forming shapes and moving in space, and molding it into a linguistic system (Emmorey, 2003; Supalla, 1986). Sign languages use classifier constructions to combine physical properties of referents with the spatial relations among them and the shape and manner of movement they execute. In this subsystem, there is a set of hand shapes that classify referents in terms of their size and shape, semantic properties, or other characteristics in a classificatory system that is reminiscent of verbal classifiers found in a variety of spoken languages (Senft, 2002). These hand shapes are the classifiers that give the system its name. An example of a classifier construction is shown in Figure 7. It describes a situation in which a person is moving ahead, pulling a recalcitrant dog zigzagging behind. The  hand shape embodies an upright human classifier and the  hand shape a legged creature.

What is unusual about this subsystem is that each formational element – the hand shape, the location,

Figure 7 Classifier construction in ASL.

and the movement – has meaning. That is, each has morphological status. This makes the morphemes of classifier constructions somewhat anomalous since sign language lexicons are otherwise built of morphemes and words in which each of these elements is meaningless and has purely phonological status. Furthermore, constraints on the cooccurrence of these elements in other lexical forms do not hold on classifier constructions. In **Figure 7**, for example, the constraint on interaction of the two hands described in the section on phonology is violated. Zwitserlood (2003) suggested that each hand in such classifier constructions is articulating a separate verbal constituent, and that the two occur simultaneously – a natural kind of structure in sign language and found universally in them, but one that is inconceivable in spoken language. Once again, sign language presents a conventionalized system with linguistic properties, some familiar from spoken languages and some modality driven.

Syntax

As in other domains of linguistic investigation, the syntax of sign languages displays a large number of characteristics found universally in spoken languages. A key example is recursion – the potential to repeatedly apply the same rule to create sentences of ever increasing complexity – argued to be the quintessential linguistic property setting human language apart from all other animal communication systems (Hausser *et al.*, 2002). Specifically, through embedding or conjoining, recursion can result in sentences of potentially infinite length. These two different ways of creating complex sentences have been described and distinguished from one another in ASL. For example, a process that tags a pronoun that is coreferential with the subject of a clause onto the end of a sentence may copy the first subject in a string, only if the string contains an embedded clause, but not if the second clause is coordinate (Padden, 1988). In example (1), the subscripts stand for person indices

marked through verb agreement, and INDEX is a pointing pronominal form, here a pronoun copy of the matrix subject, MOTHER. (These grammatical devices were illustrated in **Figures 5 and 6**.)

- (1a) MOTHER SINCE_i PERSUADE_j SISTER
 _jCOME_i INDEX
 ‘My mother has been urging my sister to come
 and stay here, she (mother) has.’
- (1b) *_iHIT_j INDEX TATTLE MOTHER INDEX.
 ‘I hit him and he told his mother, I did.’

The existence of strict constraints on the relations among nonadjacent elements and their interpretation is a defining characteristic of syntax. A different category of constraints of this general type concerns movement of constituents from their base-generated position, such as the island constraints first put forward by Ross (1967) and later subsumed by more general constraints. One of these is the WH island constraint, prohibiting the movement of an element out of a clause with an embedded WH question. The sentence, *Lynn wonders [what Jan thinks]* is okay, but the sentence **It’s Jan that Lynn wonders [what — thinks]* is ruled out. Lillo-Martin (1991) demonstrated that ASL obeys the WH island constraint with the sentences shown in example (2). Given the relative freedom of word order often observed in sign languages such as ASL, it is significant that this variability is nevertheless restricted by universal syntactic constraints.

- (2a) PRO DON’T-KNOW [‘WHAT’ MOTHER
 LIKE].
 ‘I don’t know what Mom likes.’
- _____t
 (2b) MOTHER, PRO DON’T KNOW [‘WHAT’
 ____LIKE].
 * ‘As for Mom, I don’t know what likes.’

The line over the word MOTHER in (2b) indicates a marker that is not formed with the hands, in this case a backward tilt of the head together with raised eyebrows, marking the constituent as a topic (t) in ASL. There are many such markers in sign languages, which draw from the universal pool of idiosyncratic facial expressions and body postures available to all human communicators. These expressions and postures become organized into a grammatical system in sign languages.

A Grammar of the Face

When language is not restricted to manipulations of the vocal tract and to auditory perception, it is free to recruit any parts of the body capable of rapid, variegated articulations that can be readily perceived and processed visually, and so it does. All established

sign languages that have been investigated use non-manual signals – facial expressions and head and body postures – grammatically. These expressions are fully conventionalized and their distribution is systematic.

Early research on ASL showed that certain facial articulations, typically of the mouth and lower face, function as adjectivals and as manner adverbials, the latter expressing such meanings as ‘with relaxation and enjoyment’ and ‘carelessly’ (Liddell, 1980). Other sign languages have been reported to use lower face articulations in similar ways. The specific facial expressions and their associated meanings vary from sign language to sign language. **Figure 8** gives examples of facial expressions of this type in ASL, ISL, and British Sign Language.

A different class of facial articulations, particularly of the upper face and head, predictably cooccur with specific constructions, such as yes/no questions, WH questions, and relative clauses in ASL and in many other sign languages. Examples from ISL shown in **Figure 9A** illustrate a yes/no question (raised brows, wide eyes, and head forward), **Figure 9B** a WH question (furrowed brows and head forward), and **Figure 9C** the facial expression systematically associated in that language with information designated as ‘shared’ for the purpose of the discourse (squinted eyes). Although some of these facial articulations may be common across sign languages (especially those accompanying yes/no and WH questions), these expressions are not iconic. Some researchers have proposed that they evolved from more general affective facial expressions associated with emotions. In sign languages, however, they are grammaticalized and formally distinguishable from the affective kind that signers, of course, also use (Reilly *et al.*, 1990).

Figure 8 Lower face articulations. (A) ASL ‘with relaxation and enjoyment.’ (B) ISL ‘carefully.’ (C) BSL ‘exact.’

Figure 9 Upper face articulations. (A) yes/no question, (B) WH question, and (C) ‘shared information.’

Observing that nonmanual signals of the latter category often cooccur with specific syntactic constructions, Liddell (1980) attributed to them an expressly syntactic status in the grammar of ASL, a view that other researchers have adopted and expanded (Neidle *et al.*, 2000; Petronio and Lillo-Martin, 1997). A competing view proposes that they correspond to intonational tunes (Reilly *et al.*, 1990) and participate in a prosodic system (Nespor and Sandler, 1999). Wilbur (2000) presented evidence that nonmanuals convey many different kinds of information – prosodic, syntactic, and semantic. A detailed discussion can be found in Sandler and Lillo-Martin (2005).

Acquisition of Sign Language

Nowhere is the ‘natural laboratory’ metaphor more appropriate than in the field of sign language acquisition. This area of inquiry offers a novel and especially revealing vantage point from which to address weighty questions about the human capacity for language. Research has shown, for example, that children acquire sign language without instruction, just as hearing children acquire spoken language, and according to the same timetable (Newport and Meier, 1985). These findings lend more credence to the view, established by linguistic research on the adult system, that languages in the two modalities share a significant amount of cognitive territory; children come equipped for the task of acquiring language in either modality equally.

Studies have also shown that signing children attend to grammatical properties, decomposing and overgeneralizing them as they advance through the system, sometimes even at the expense of the iconic properties inherent in that system. For example, even the pointing gesture used for pronouns (see **Figure 5**) is analyzed as an arbitrary grammatical element by small children, who may go through a stage in which they make mistakes, pointing at ‘you’ to mean ‘me’ (Pettito, 1987). Meier (1991) discovered counter-iconic errors in verb agreement (see **Figure 6**), similarly indicating that children are performing a linguistic analysis, exploring spatial loci as grammatical elements and not as gestural analogues to actual behavior and events.

Due to the social conditions surrounding its acquisition, sign language lends novel insight into two key theories about language and its acquisition: the critical period hypothesis and the notion that the child makes an important contribution to the crystallization of a grammar. Some deaf children are raised in oral environments, gaining access to sign language later in life. Studies comparing the ASL performance of early and late learners found that the age

of exposure is critical for acquisition of the full grammatical system (Newport, 1990) and its processing (Mayberry and Eichen, 1991), providing convincing support for Lenneberg's (1967) critical period hypothesis. An untainted perspective on the child's contribution can be gained where the input to the child is simpler and/or less systematic than a full language system, as with pidgins (Bickerton, 1981). Researchers of the sign language that originated in the Nicaraguan school mentioned previously studied the communication system conventionalized from the home sign brought to the school by the first cohort of children. This system served as input to the second cohort of children younger than the age of 10 years who later arrived at the school. Comparing the language of the two cohorts, the researchers found that children make an important contribution: The second cohort of signers developed a significantly more structured and regular system than the one that served as their input (Kegl *et al.*, 1999; Senghas *et al.*, 2004).

Sign Language and the Brain

Broadly speaking, it is established that most spoken language functions involve extensive activity in specific areas of the left hemisphere of the brain, whereas much of visuospatial cognition involves areas of the right cerebral hemisphere. Therefore, the discovery that sign language, like spoken language, is primarily controlled by the left hemisphere despite its exploitation of the visuospatial domain is striking and significant (Emmorey, 2002; Poizner *et al.*, 1987). Various explanations for left hemisphere dominance for language are currently on the table, such as the more general ability of the left hemisphere to process rapidly changing temporal events (Fitch *et al.*, 1997). This explanation has been rejected for sign language by some researchers on the grounds that sign language production is slower than that of spoken language (Hickock *et al.*, 1996). Whatever explanation is ultimately accepted, Emmorey (2002) and others have argued that similarities in the kind of cognitive operations inherent in the organization and use of language in the two modalities should not be ignored in the search.

Although most language functions are controlled by the left hemisphere, some do show right hemisphere involvement or advantage. With respect to sign language, there is evidence that the right hemisphere may be more involved in producing and comprehending certain topographic/spatial aspects of sign language, particularly those involving classifier constructions (Emmorey *et al.*, 2002). Although this result sits well with the known right hemisphere

advantage for spatial processing, it is made even more interesting when added to discoveries of right hemisphere dominance for certain other spoken and sign language functions that may be related to the classifier system, such as processing words with imageable, concrete referents (Day, 1979; Emmorey and Corina, 1993). Findings such as these are an indication of the way in which sign language research adds important pieces to the puzzle of language organization in the brain.

Language Modality, Language Age, and the Dinner Conversation Paradox

A large body of research, briefly summarized here, attributes to sign languages, essential linguistic properties that are found in spoken languages as well (Sandler and Lillo-Martin, 2005). Also, like different spoken languages, sign languages are not mutually intelligible. A signer of ISL observing a conversation between two signers of ASL will not understand it. Although cross sign language research is in its infancy, some specific linguistic differences from sign language to sign language have already been described.

At the same time, there is a rather large group of predictable similarities across sign languages and, as Newport and Supalla (2000: 109) stated, "A long dinner among Deaf users of different sign languages will, after a while, permit surprisingly complex interchanges." Here we find a difference between signed and spoken languages: One would hardly expect even the longest of dinners to result in complex interchanges among monolingual speakers of English and Mandarin Chinese. Although it is clear that more differences across sign languages will be uncovered with more investigation and more sophisticated research paradigms, it is equally certain that the dinner conversation paradox will persist. Two reasons have been suggested for crosssign language similarities: the effect of modality on language structure and the youth of sign languages.

Modality Effects

Modality is responsible for two interwoven aspects of sign language form, both of which may contribute to similarities across sign languages: (i) an iconic relation between form and meaning, and (ii) simultaneity of structure. Because the hands can represent physical properties of concrete objects and events iconically, this capability is abundantly exploited in sign languages, both in lexical items and in grammatical form. Although spoken languages exhibit some iconicity in onomatopoeia, ideophones, and the like, the vocal-auditory medium does not lend itself to direct correspondence between form and meaning so that

Figure 10 An iconic sign: (ISL) BOOK.

the correspondence in spoken language is necessarily more arbitrary.

Iconicity in Sign Language Leafing through a sign language dictionary, one immediately notices the apparent iconicity of many signs. An example is the ISL sign for BOOK, shown in Figure 10, which has the appearance of a book opening. Although clearly widespread, iconicity in sign language must be understood in the right perspective (*see Iconicity*). Many signs are not iconic or not obviously motivated, among them the signs for abstract concepts that exist in all sign languages. Interestingly, even the iconicity of signs that are motivated is not nearly so apparent to nonsigners if the translations are not available (Klima and Bellugi, 1979). In addition, the presence of iconicity in sign language does not mean that their vocabularies are overwhelmingly similar to one another. In fact, although even unrelated sign languages have some overlap in vocabulary due to motivatedness, their vocabularies are much more different from one another than one might expect (Currie *et al.*, 2002). Nevertheless, the kind of symbolization and metaphoric extension involved in creating motivated signs may be universal (Taub, 2001). For example, a bird is represented in ISL with a sign that looks like wings and in ASL with a sign that looks like a beak, and experience with this kind of symbolization in either sign language may make such signs easier to interpret in the other.

Simultaneity in Sign Languages Another modality feature is simultaneity of structure, alluded to previously. Some researchers have argued that constraints on production, perception, and short-term memory conspire to create simultaneity of linguistic structure (Bellugi and Fischer, 1972; Emmorey, 2002). Interestingly, iconicity also makes a contribution to simultaneity of structure, especially when one looks beyond the lexicon to grammatical forms of a more complex nature.

The hands moving in space are capable of representing events that simultaneously involve a predicate

and its arguments (e.g., giving something to someone or skimming across a bumpy surface in a car) with a form that is correspondingly simultaneous. The result is verb agreement (exemplified in Figure 6) and classifier constructions (exemplified in Figure 7). Therefore, these structures, with particular grammatical properties, are found in all established sign languages that have been studied, leading to the observation that sign languages belong to a single morphological type (Aronoff *et al.*, 2005). Although the grammatical details of this morphology differ from sign language to sign language, the principles on which they are based are the same, and this similarity makes another welcome contribution at the dinner table.

The Role of Language Age

Recent work pinpoints the role of language age in the structure of sign language, indicating how age may be partly responsible for the impression that crosssign language differences are less abundant than is the case across spoken languages. It does so by comparing the type of morphology ubiquitously present in sign languages with a language-specific type (Aronoff *et al.*, 2005). This study noted that the form taken by the verb agreement and classifier systems in all established sign languages is similar (although not identical) due to the modality pressures of iconicity and simultaneity sketched previously, but that sequential affixes of the kind exemplified in Figure 4 vary widely between the sign languages studied. Such affixes, arbitrary rather than iconic in form and limited in number, develop through grammaticalization processes, and these processes take time. Given time, more such arbitrary, sign language-specific processes are predicted to develop.

The physical channel of transmission affects language in both modalities. Where sign languages are more simultaneously structured, spoken languages are more linear. Where spoken languages are mostly arbitrary, sign languages have a good deal of iconicity. However, none of these qualities are exclusive to one modality; it is only a matter of degree.

Sign Languages of the World

The Current State of Knowledge

After more than 30 years of systematic sign language research, most sign languages throughout the world still remain scarcely documented or even entirely unknown. We can only estimate how many sign languages exist in the world, and we are even less sure about how they may be grouped into language families. A few sign languages in industrialized countries are reasonably well documented, whereas little is known about sign languages in other areas of the world, such as sub-Saharan Africa, Southeast Asia, and the Arab world. Nevertheless, increasingly more information has been coming to light during the past decade, although we are still far away from systematic linguistic documentation in most cases.

Based on what we know to date, it is fairly clear that the sign languages of the world number in the hundreds rather than in the thousands and are thus much fewer in number than their spoken counterparts. For all we know, they are also much younger than spoken languages, although other forms of gestural communication are as old as humanity itself. The 2004 edition of the *Ethnologue* (Grimes, 2004)

lists approximately 100 living sign languages. However, there are many omissions and errors in this list, so the actual number of sign languages in the world is likely to be at least three or four times greater.

The maximum documented age for a sign language is slightly more than 500 years for the sign language used at the Ottoman court in Turkey (Miles, 2000). There is no reason why the large cities of antiquity more than 2000 years ago should not have had groups of sign language users, but we do not have any reliable sources for these times. On the other hand, it is quite unlikely that communities of sign language users as we know them today would have existed even earlier. Only after urbanization had created reasonably large populations could critical numbers of deaf people theoretically have come together to use a sign language.

For many known sign languages, there is more or less detailed anecdotal evidence of historical links with other sign languages. These links may have to do with colonial history, migration of populations, or, in more recent times, the establishment of deaf education with the help of another country. The principal difficulty lies in determining whether a particular relationship between sign languages is genetic in nature (i.e., in how far we can speak of a sign language family) or whether we are dealing with a language contact situation. Attempts at addressing this issue

have been largely unsuccessful, and no theoretically sound method of investigating historical relationships between sign languages is available.

In recent years, increasingly more sign languages are beginning to be documented. A first step is usually the compilation of basic vocabulary in word lists (pairing a word and a picture of a sign), which are often wrongly called 'dictionaries' (see **Figure 1**). During the past decade, these and other developments have resulted in a situation in which it is now possible to systematically compare linguistic structures across a much wider range of sign languages than in the past. The newly emerging field of sign language typology is concerned with the issue of how to systematize this new knowledge in a theory of variation across sign languages.

Sociocultural and Sociolinguistic Variables

Signed communication occurs in a variety of situations. This article is concerned exclusively with natural full-fledged sign languages that are the primary languages of their users. We are not concerned with artificially created sign systems such as 'Manually Coded English,' 'Signed Japanese,' and 'Dutch in Signs,' which have been invented for educational purposes with the aim of mirroring spoken language structures 'on the hands'. We are also not concerned with secondary sign languages that are used in communities where the usual mode of communication is through a spoken language but where signed communication plays a supplementary role for certain purposes, such as conditions of speech taboo. Rather, the sign languages we are interested in involve groups of deaf people for whom the sign language is the primary means of communication.

The first sign languages that were documented in detail from the 1970s onwards are used by communities of deaf people in urban settings. These are minority languages in which most of the users are deaf and there is constant language contact with the surrounding spoken/written language of the majority culture of hearing people. This situation is well described and occurs in urban areas in all regions of the world.

However, sign languages also exist in an entirely different sociocultural setting that is less well documented but highly significant for cross-linguistic comparison. These sign languages are used in village communities with a high incidence of hereditary deafness. Village-based sign languages arise because deaf individuals have been born into the village community over several generations, and therefore a sign language has evolved that is restricted to the particular village or group of villages. These sign languages are

typically used by the whole village population no matter whether deaf or hearing, and in this sense, they are not minority languages, nor do they face any linguistic oppression. They have developed in isolation from other sign languages and are not used in any educational or official context. Deaf people are fully integrated into village life and may not be considered to be 'disabled' in any sense (Branson *et al.*, 1999). The existence of village-based sign languages has been reported from places as diverse as Bali, Ghana, Thailand, Mexico, an Arab Bedouin tribe in Israel, and a native Indian tribe in the Amazon, but their linguistic documentation is only just beginning. These languages have the potential to call into question many of the general assumptions that were made previously about the structure of sign languages.

Some village-based sign languages are already endangered and have not been documented in detail. As the larger, urban sign languages move in through formal education and the media, these small, locally restricted sign languages face similar pressures as their spoken language counterparts (see **Endangered Languages**). Similarly, sign languages in some developing countries have been under pressure from foreign sign languages, as in many African countries. In places where the deaf community is very large and the indigenous sign language has had time to develop on its own, it is relatively immune to foreign influences, as is the case in China and in the Indian subcontinent.

Despite similarities with respect to language endangerment, the life cycle of sign languages also differs from that of spoken languages in that new sign languages continuously emerge throughout the world, as most famously documented in Nicaragua (Kegl *et al.*, 1999). Throughout the world, urbanization and the spread of special education for the deaf create new deaf communities with newly emerging sign languages. The stage of a sign language's life cycle is an important consideration for comparing the structures of sign languages.

Relationships between Sign Languages

For a number of individual sign languages as well as groups of sign languages, the notion of sign language family has been proposed, based on known facts about their relationship with each other. For example, it is well-known that sign language was brought to New Zealand and Australia from the United Kingdom, and therefore these three sign languages make up the 'British Sign Language family.' For different historical reasons, the Japanese Sign Language family includes sign languages in Taiwan and Korea, both of which had been under Japanese occupation. In cases in which one and the same sign language-using

community seems to have split and subsequently developed independently from each other, the traditional family tree model can be applied, and the shared history is visible and interpretable. Sign languages in Australia, New Zealand, and the United Kingdom are still mutually intelligible to a large extent and share most of their vocabulary, to the extent that it is doubtful whether they should not be classified as dialects of one and the same language. Sign languages in Korea, Japan, and Taiwan all share a peculiar grammatical mechanism of gender marking, with the thumb indicating male and the little finger female gender as formative elements in complex signs (see Figure 2). This feature is not found in any other known sign language and, together with other factors, makes a strong case for positing a shared history of this sign language family.

However, the situation is usually not so clear-cut. In most cases, it is impossible to determine whether similarities between two sign languages are the result of a genetic relationship or the result of language contact. Instead of the 'pure' kind of family tree relationship, a more common type of relationship between two sign languages involves various kinds of language contact situations, language mixing, and creolization. For example, American Sign Language is said to have arisen in a creolization process, where Old French Sign Language came in contact with indigenous sign varieties, resulting in a new language with input from both of these sources. This kind of relationship cannot be considered genetic in the usual sense of the term.

In many cases, there is more or less clear historical evidence of relationships between sign languages. This may be related to colonial history so that, for instance, sign language communities in the Indian subcontinent use a two-handed manual alphabet as in British Sign Language. However, actual historical documentation of how this came to be the case is lacking, there are very few meaningful similarities in

the vocabulary and grammar of the two sign languages, and there is thus no evidence for including Indo-Pakistani Sign Language in the British Sign Language family. Another common factor in linking two sign languages often involves the establishment of educational facilities for the deaf. For instance, the sign language in Brazil is said to have its root in French Sign Language because a deaf Frenchman established the first school for the deaf in Brazil, and Swedish Sign Language was similarly brought to Finland. We find this kind of link between many African countries and one or more Western 'source' sign languages (Schmaling, 2001). American Sign Language (ASL) has had a major impact on deaf communities in other countries, such as Thailand, the Philippines, Uganda, Zambia, Ghana, Malaysia, and Singapore, and it is often unclear whether the sign languages used in these countries should be considered dialects of ASL, descendants of ASL in a family tree of languages, ASL-based creoles, or independent sign languages with extensive lexical borrowing from ASL. To the extent that indigenous sign languages already existed in these countries and secondarily came under the influence of a foreign sign language, the relationships between them are not genetic in the usual sense but are instances of language contact.

This kind of problem is not unknown for spoken languages but is aggravated by a number of complicating factors in the case of sign languages. First, the familiar historical-comparative method that is used to determine language families and reconstruct older forms of source languages has never been applied to sign languages. No process of regular sound change has been identified, and the comparison of morphological paradigms is often compromised because the forms in question are iconically motivated. Vocabulary comparisons are highly unreliable, and there seems to be a considerable 'baseline level' of iconically determined lexical similarity even between unrelated sign languages (Guerra Currie *et al.*, 2002).

Figure 2 Gender marking in South Korean Sign Language: SCOLD(someone), SCOLD(me), SCOLD(a male person), SCOLD(a female person).

The first family trees that were proposed for sign languages were based on historical evidence and lexical similarities, and later attempts at using glottochronology on the basis of word list comparisons (Woodward, 1993, 2000) are similarly unreliable.

Another complicating factor in many cases is the uncertainty about whether or not there were indigenous sign varieties before the influence of a foreign sign language set in and, if so, what the linguistic status of this signed communication might have been. It is possible that in a particular region, limited home sign systems came in contact with a foreign full-fledged sign language, resulting in a new sign language in a process that has no counterpart among spoken languages. Finally, the lack of any historical records makes it difficult to directly test and evaluate any proposed historical relationship between sign languages. In the absence of any sound methodology for establishing sign language families, the issue of how one sign language is related to another one usually remains unresolved.

Grammatical Similarities and Differences across Sign Languages

Over time, sign language linguists have come to expect certain features in the structure of sign languages that have been shown to occur with great regularity in most or all sign languages known and described so far. Accordingly, there are attempts at accounting for these putative sign language universals on the basis of their visual-gestural modality. For instance, sign languages offer the possibility of using spatial grammatical mechanisms by virtue of being three-dimensional languages, and therefore they tend to use movement modifications to express aspectual distinctions or to use movement direction to code verb agreement. Since the articulators in sign language are larger and slower than in a spoken language, sign languages tend to mark grammatical functions in a simultaneous rather than a sequential fashion; therefore, they use nonmanual behaviors such as facial expressions to mark sentence types (questions, negation, and

subordination), and they use complex signs with numeral incorporation (e.g., a single complex sign meaning ‘three months’). It has been claimed that sign languages are similar in the kinds of complex simultaneous morphology just mentioned but differ from each other in sequential morphology such as clitics and affixes, with sequential morphology being comparatively rare in sign languages (Aronoff *et al.*, 2000).

Most of these generalizations about the similarities between sign languages are based on investigations of a limited number of languages, mainly in Europe and North America. The picture changes somewhat when examining a larger range of the world’s sign languages. Although the previous observations are indeed true of many sign languages throughout the world, this is only part of the story. First, some sign languages do not show the ‘expected’ types of structures. Two unrelated village-based sign languages, in Bali and Israel, do not show an elaborate system of spatial verb agreement as is familiar from other sign languages. Another village-based sign language in Ghana does have spatial verb agreement but does not use the so-called ‘classifier’ hand shapes to refer to categories of moving persons, animals, and vehicles. Given that village-based sign languages have developed in isolation from any other sign language and exist under very different sociolinguistic conditions, it is not unexpected to find important differences in their structures in comparison with urban sign languages.

The range of possible structures in sign languages expands considerably when we consider non-Western, lesser-known sign languages. The gender marking system in the Japanese Sign Language family represents one such example. Sign language varieties in China also show many particularities that are not familiar from documented Western sign languages. Chinese Sign Language varieties include so-called ‘character signs,’ a particular type of borrowing in which the shapes and movements of the hands imitate the whole or part of words from the Chinese writing system (see Figure 3). Both northern and southern

Figure 3 Character signs in Chinese Sign Language.

sign language varieties in China also make use of a productive mechanism of negation in which negative signs are marked by an extended little finger and the positive counterparts have an extended thumb (see **Figure 4**). Finally, question words for quantifiable concepts include one or two open hands with finger wiggling as part of complex signs, forming a large paradigm of interrogatives. The study of a greater range of sign languages thus reveals a large number of previously undocumented grammatical structures, just as the study of 'exotic' spoken languages did in earlier stages of spoken language linguistics.

Other structural differences between sign languages are more subtle and only come to light after systematic investigation. Typologically oriented studies across sign languages exist for a limited number of grammatical domains (for pronouns, see McBurney, 2002; for questions and negation, see Zeshan, 2004a, 2004b). Such studies show that the degree of structural differences between sign languages may be considerable but is unevenly distributed across different parameters of investigation. For example, sign languages differ as radically as spoken languages with respect to the set of their possible question words. A sign language may have only a single question

Figure 4 Chinese Sign Language signs with "little finger" negative morpheme: DEAF and TASTELESS.

word, as in certain dialects of Indo-Pakistani Sign Language (see **Figure 5**), or more than a dozen, as in Hong Kong Sign Language. On the other hand, the facial expressions accompanying questions tend to be very similar across unrelated sign languages, with eye contact, forward head position, and eyebrow movement as prominent features. Understanding the reasons for these patterns is important for building a theory of typological variation across sign languages.

Another important result from comparative studies is that certain sign language forms may look very similar superficially but in fact have very different properties. For instance, in a broad range of 38 sign languages throughout the world (see **Figure 6**), it has been found that in each case, negation can be expressed by a side-to-side headshake (Zeshan, 2004a). However, the grammatical constraints governing the use of headshake negation in fact differ greatly across sign languages. Whereas in some sign languages, such as in the Scandinavian region, headshake negation is a primary negation strategy and may often be the only instance of negation in the clause (Bergman, 1995), other sign languages, such as in Japan and Turkey, obligatorily use a manual negative sign with or without headshake negation as a secondary accompaniment. Sign languages in the eastern Mediterranean region (Greece, Turkey, and neighboring Arab countries) additionally use a single backward head tilt for negation that has not been found in any other region of the world (Zeshan, 2002).

It can be assumed that the significance of many possible parameters of variation across sign languages has not been recognized. For example, mouth movements deriving from a silent representation of spoken words, so-called 'mouthing,' carry an important functional load in some sign languages (e.g., in Germany, The Netherlands, and Israel) but are functionally largely irrelevant in Indo-Pakistani Sign Language (Boyes Braem and Sutton-Spence, 2001). The presence or absence of contact with literacy may be another important factor, evidenced by the

Figure 5 Combinations with the Indo-Pakistani Sign Language question word (WH): PLACE+WH "where", TIME+WH "when".

Figure 6 Sign languages represented in the typological survey on questions and negation.

fact that not all sign languages use an indigenous manual alphabet for fingerspelling.

Future Developments

The dynamics of developments throughout the world with respect to sign languages and their documentation carry considerable momentum. Some sign languages are endangered, whereas others are expanding in geographical spread and contexts of use, and some are only just being created by new communities of users. Forces such as intensive contact between sign language and spoken language, as well as between one sign language and another, and the move toward official recognition for sign languages and the deaf communities that use them rapidly change and reshape the makeup of many sign languages worldwide. It is a continuous challenge for sign language linguistics to keep up with these developments and put together an increasingly detailed picture of linguistic diversity among the world's sign languages.

Sign Languages: Discourse and Pragmatics

R B Wilbur, Purdue University, West Lafayette, IN, USA

Culture and the Pragmatics of Discourse

In every culture, conversations have structures that reflect their values, for example, whether the information provided is truthful, or satisfies the questioner, or is polite. As an example, Weiser (1975) notes that an answer can be acceptable in discourse if the answer addresses the questioner's purpose for asking the question. She illustrates this with (1):

(1) Q: How old are you?

A: Don't worry, they'll let me in.

The questioner thinks something like: We are going to a bar; there is a minimum age of 21 to get in; I wonder if my date is old enough. The questioner asks for specific information. The date responds with reassurance that his underlying concern will not be a problem. The date's age remains a mystery. Such a conversation is considered polite in a culture that places high value on not invading a person's privacy by requesting personal information, such as age.

Conversational style and structure differ significantly between Deaf and hearing communities. Because signers can see, and be seen by, anyone who is present, it is especially difficult to maintain privacy.

Furthermore, as Hall (1989) observes, the Deaf community functions as a surrogate family – everyone knows everyone. The politeness conventions that dominate Deaf community interactions help promote unity among the Deaf. Since maintaining privacy is problematic, conversations among Deaf people lean toward the opposite – being more direct, which may feel intrusive to people unfamiliar with this cultural priority. Attempts at evasive answers may lead to joking, teasing, and not-so-subtle prodding.

Minority Language Status and Signing Style in Discourse

As with spoken languages, there are sign register differences, such as formal/informal articulation, larger signing and signing space when 'shouting' across the room, and so on. Signing style is also heavily affected by its minority language status, especially when hearing people are present. If the hearing people are supposed to be conversational participants but do not know sign, signers may switch to voice and speak the dominant spoken language, or they may resort to writing with paper and pen. Others may continue to sign, but in an altered form that involves speaking while putting the signs into the word order of the dominant language (known as 'signed English,' 'signed Croatian,' etc.). Such

simultaneous speaking and signing is a hybrid communication technique that distorts both speech and signing, and is not itself a natural language (Wilbur and Petersen, 1998). If the hearing people do know some signing, Deaf signers may continue in their own sign language, but with a slowed signing rate, and perhaps with altered choice of signs. There is a signing style (rate of signing, lexical choice, use of facial expressions) reserved for use among members of the Deaf community.

Modality Effects on the Pragmatics of Discourse Structure

Conversations in sign language always take place face-to-face, even when facilitated by new technology such as web cameras that allow signers to be seen across great distances. Face-to-face interaction is likely to be infrequent among people who live at distances from each other, and may be limited in duration. This may be the reason for a prominent characteristic of signed conversations, namely, that they start informally, get right to the point, and conclude formally and slowly (Hall, 1989 for ASL). In contrast, American speakers of English begin formally and slowly, conclude informally and quickly, and tend not to be direct about getting to the main point.

Getting Attention

Conversations in SLs require the participants to be paying attention to each other. Ways to obtain attention include waving at or tapping someone, or enlisting a third person to help with this procedure. In larger groups, the lights may be flicked off once or twice to get everyone's attention.

Saying Good-bye

It takes a while to say good-bye to each person in a conversation or large gathering. Saying good-bye ends a face-to-face interaction, leaving communication to be resumed at some uncertain future time. Thus, saying good-bye includes some discussion of when that might be, such as other upcoming events.

Turn Taking

Hand Position Given that all interaction is face-to-face, an orderly system of turn taking is necessary to ensure that participants do not miss part of the communication. Baker (1977) observed regulators that mark turns within conversations, such as hand position. When a signer is listening and not intending to take a turn, the hands are down. When a signer is preparing to sign, perhaps to interrupt or waiting for a turn but wants the current signer to acknowledge

that he is waiting, the hands assume half-rest position, generally at waist level. Hands higher than this are in quarter-rest position, a strong indication to the current signer to yield the floor. Of course, a signer can simply begin to sign and hope that the other signer will yield the floor. The floor is yielded by returning hands to full-rest or half-rest position as an indication of wanting the floor back.

Nonmanuals Eye contact plays a significant role in regulating conversational turns. A conversation cannot begin without eye contact between participants, after which the addressee must continue to watch the signer, but the signer is free to look away, for organizing thought or maintaining the floor. As in speech, the signer must check back with the addressee to be certain that the addressee is following the conversation. A signer can ignore an interruption by not establishing eye contact with the person attempting to interrupt (Baker, 1977).

Information Flow and Discourse Structure

Information Flow and Focus

The presentation of information in a discourse is structured according to the sender's belief regarding the receiver's knowledge and attentional state (whether something is in the receiver's mind at the time). Gundel (1999) separates three types of 'focus': psychological 'salience'; semantic 'new information'; and contrastive focus. Psychological focus is what the sender and addressee are attending to. Joint attention ensures that what is the current center of attention is salient to both partners, making it old or given: the 'topic' of conversation. Linguistically, nonfocused information tends to be referred to with pronouns (which refer back to something), definite articles ('the') in languages that have them, and pro-drop in languages that allow it (that is, not expressed at all in the sentence).

In contrast, the term 'focus' is used to refer to new information. By definition, all sentences have new information (Gundel's 'semantic focus'). This is the assertion of the utterance; that part which cannot be deleted. Other terms used for the new information include 'comment' in topic-comment constructions, and 'rheme' in theme-rheme constructions. The term 'focus' will be used here.

Focus Prominence Placement and Marking

Broad Focus Every language has a procedure for determining (a) where the stress prominence falls in a 'neutral' sentence, that is, one that is entirely in focus; and (b) how the prominence will be marked

phonetically. When the whole sentence is in focus, stress may be placed on whatever word happens to occur in a particular position, such as final. Or it may be placed on the last lexical item, ignoring functional words. Other strategies include placing it on the last argument of the predicate, or if that argument is a phrasal constituent, on the lexical head of the phrase.

In spoken languages, the marking of linguistic stress itself may include increased duration of the prominent item, higher fundamental frequency (pitch), and increased amplitude. SLs do not have access to pitch. Research on ASL shows that it uses increased peak velocity of signed movement for stress prominence, and uses increased duration of signs primarily for Phrase Final Lengthening (Wilbur, 1999). ASL also has many other cues to indicate stress, including nonmanuals of head and eyes, and body leans, discussed below.

Narrow Noncontrastive Focus When the whole sentence is not in focus, a variety of distinctions are made. The first is Gundel's 'semantic' focus or what Dik (1989) calls 'completive' focus. This is the part of the sentence that provides the relevant new information; if someone asks 'What flavor do you want?' and the answer is 'I want chocolate,' 'chocolate' is the focused part of the sentence and 'completes' the exchange. A second is focus particles, such as 'even,' 'only,' 'both,' and 'also,' which are traditionally distinguished as lexical focus markers; the items they focus on are called 'focus associates.' In ASL, the sign glossed as SAME functions as 'even,' and ONLY-ONE as 'only.' The focus associates may precede or follow the particle; if it precedes, a brow raise is required on the associate but not on the focus particle. A third is intensive focus, which uses reflexives, e.g., 'Only the defendant *herself* remained completely calm.' In ASL, the sign SELF is used for this.

Narrow Contrastive Focus A more emphatic type is 'contrastive' focus. Gundel argues that contrastive focus is used "because the speaker/writer doesn't think the addressee's attention is focused on a particular entity and for one reason or another would like it to be, because a new topic is being introduced or reintroduced (topic shift), or because one constituent (topic or semantic focus) is being contrasted, explicitly or implicitly, with something else" (Gundel, 1999: 296). By this definition, 'topics' can be 'focused' when they are new or reintroduced.

When contrastive focus selects a correct form from a closed and known set (Dik's 'selecting' focus), ASL uses a lean forward on the selected item. If the

question is 'Do you want vanilla, chocolate or strawberry?' (a closed set) and the answer is 'I want strawberry,' it is 'strawberry' that is 'selected' or contrasted with the other items. When 'replacing' focus is involved ('chocolate' not 'strawberry'), a lean forward is used to mark the correct response 'chocolate' and lean backward is used to mark the rejected response 'strawberry.' When two items in the same sentence are contrasted with each other ('and/or/but'), 'parallel' focus is involved and ASL uses left/right leans as well as forward/backward leans.

Syntactic Mechanisms of Focus Marking

Contrastive focalization ('topicalization') is the movement of a constituent to sentence initial position for purposes of contrasting it with a previously mentioned item. Aarons (1994) gives example (2):

- (2) $\text{JOHN}_i \text{ NOT-LIKE JANE. MARY}_j, \text{ HE}_i \text{ LOVES } \emptyset_j$
'John doesn't like Jane. It's Mary he loves.'

Another syntactic focus construction is the cleft ('It was a new sweater that Kio gave Mia for her birthday'). ASL uses the focus sign THAT in the cleft, with nonmanual marking (brow raise) on the focused nominal ('a new sweater'), which must precede THAT. When the sequence THAT NP does occur, its interpretation is purely demonstrative ('that man'), and no brow raise is used.

Languages also have syntactic constructions that put words or phrases in focus, such as the wh-cleft ('What Kio gave Mia for her birthday was a new sweater'). The wh-cleft (so-called 'rhetorical question') is particularly useful for focusing large constituents ('sterilize surgeon's tools'):

- (3) $\text{ELLEN WORK DO++ WHAT, CLEAN}$
 $\text{STERILIZE SURGEON POSSESSIVE}$
 TOOLS
'What Ellen does for a living is sterilize surgeon's tools.'

Language Typology for Focus

When only part of the sentence is in focus, some languages may move the prominence marking to the focused item ([+plastic], Vallduví, 1991, 1995). English is plastic in this sense, as seen in (4), where bold indicates prominence:

- (4a) Juan saw Mariko **leave** the party early.
(4b) Juan saw **Mariko** leave the party early.

In contrast, nonplastic languages, such as Catalan, have reserved locations for focus, usually in sentence

initial, preverbal, or final position. The word order may be changed in order to put different focused items in the reserved position. In ASL, the wh-cleft puts the focused material in final position and uses brow raise on the nonfocused part (5) (Wilbur, 1997, 1999).

- (5) *br*
 (i) HELENA SEE KIM PUT BOOK WHERE, TABLE
 'The place where Helena saw Kim put the book was the table.'
br
 (ii) HELENA SEE KIM PUT-ON-TABLE WHAT, BOOK
 'What Helena saw Kim put on the table was the book.'
br
 (iii) HELENA SEE BOOK PUT-ON-TABLE WHO, KIM
 'The person who Helena saw put the book on the table was Kim.'
br
 (iv) HELENA SEE KIM DO++, BOOK PUT-ON-TABLE
 'What Helena saw Kim do was put the book on the table.'

Common Sign Language Structure for Emphasis

Finally, linguistic prominence for 'emphasis' can be separated from focus. While focused items may also be emphasized, not all emphasized items are focused. SLs frequently have a process of 'copying' or 'doubling' certain lexical categories, including modals, negation, wh-words, subject pronouns, quantifiers, and numerals. Such doubling of signs often leads nonsigners to erroneously conclude that sign languages are just repetitive gestures with no systematic structure. But typically, a doubled item will occur sentence initially or in its in situ position, and the double will occur sentence finally. Items such as these are not new information or in focus. The repetition of them by doubling serves to emphasize them as important (but not as new) (Petronio, 1993).

Sign Languages: Semiotic Approaches

W C Watt, University of California, Irvine, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

'Sign languages,' or 'gestural languages,' mostly arise in place of voice languages when voice languages are unavailable to people because they are profoundly deaf, because they speak different languages that are mutually unintelligible, or because speaking is barred by custom. ('Gestures' in this context include facial expressions.) Examples are the gestural language of the American deaf – 'Ameslan' or 'ASL' (American Sign Language) – and the gestural languages of the American Plains Indians and of certain monks sworn to silence. A gestural language is a language just as English is; lesser gestural systems such as the signals used by traffic cops or landing signal officers on aircraft carriers do not offer a sufficiently rich repertoire of signs – or above all, a syntax – to enable their users to convey whatever they wish. A landing signal officer can convey 'OK to land' but not, as English can so easily, 'A two-mile-long aircraft carrier has just been commissioned that can land 747s.'

Because gestural languages mainly use hand gestures to produce their sentences and eye recognition to receive them, they differ significantly from voice languages produced by the vocal tract and received by the ear. For example, voice languages convey much by intonation and stress – thereby distinguishing between 'You've been to Paris' and 'You've been to *Paris*?' – while in a gestural medium, these are conveyed by gestures alone.

True gestural languages must be distinguished, not only from the communications available to traffic cops and the like, but also from another limited medium, the 'fingerspelling' that the deaf sometimes resort to. Fingerspelling, whether assigning areas on

one hand to stand for a letter to be pointed at by the forefinger of the other (Dalgarno, 1680), or more directly indicating the letters with finger configurations (often mimicking letter shapes) (Stokoe, 1974), is only a way of conveying the spelling of some voice language (e.g., English). In contrast, Ameslan is quite independent of American English (and differs from its British counterpart). Their autonomy is another criterion by which gestural languages can be judged 'true languages.'

Gestural languages combine partial gestures that are functionally equivalent to phonemes (West, 1960: vol. I, 9–18) to form morphemes and words. These partial gestures are variously called 'cheremes' or 'kinemes' and are syntactically structured into sentences. Thus, the Ameslan morpheme 'girl' is gesturally conveyed, rather than by the four phonemes /g/, /ʌ/, /r/, and /l/, by three concurrent 'cheremes' characterized as 'drawing down,' 'the ball of the thumb,' and 'along the cheek' (Nöth, 1990: 284). Despite their structural similarities, however, other gestural languages typically have less expressive power than those of the deaf.

Gestural languages have been studied in depth by linguists, other semioticians, amateur and professional anthropologists, psychologists, and neurologists, whether they are used by the deaf (e.g., Bellugi and Studdert-Kennedy, 1980, esp. 29–40, 115–140, 291–340), by people lacking other inter-tribal communicative means (Umiker-Sebeok and Sebeok, 1978), by people who must abjure speech when orating stories or rituals (West, 1960: vol. II, 9, 62, 68), or by people for whom speech is taboo, such as certain monks (Umiker-Sebeok and Sebeok, 1987) and newly widowed Aboriginal women (Kendon, 1980).

Silence

A Jaworski, Cardiff University, Cardiff, UK

© 2006 Elsevier Ltd. All rights reserved.

What monochrome painting, in its richness and multitude of manifestations is to history of art, silence is (or should be) to linguistics. Functionally, the question what silence 'does' is best answered in the same way as is the question what speech, or any other semiotic system, can 'do' in communication. Taking Halliday's (1978) view of semiotic systems, for example, silence can be shown to fulfill three major functions: ideational, interpersonal and textual (*see Systemic Theory; Halliday, Michael Alexander Kirkwood*). In its ideational function, i.e., describing or referring to the nonlinguistic reality, silence's primary function is to conceal information. But it can also allow ideational inferences to be made, as when a silent response follows a request for information. Consider the following (constructed) example:

- A: Who ate all the cookies?
 B: [silence]
 A: I knew you did!

Not unlike other forms of nonverbal communication, what silence serves best is the interpersonal function, i.e., managing social actors' relations of power and solidarity. Thus, silence can either mark interpersonal intimacy or extreme distance in situations where 'small talk' is normally required between casual acquaintances (Jaworski, 2000); alternatively, it may signify an extreme power differential between interactants (Braithwaite, 1990) (*see Power and Pragmatics*). In its textual function of organizing coherence, or the framing of talk, pauses are often used to add emphasis to what is going to be said next (Duez, 1982), or they may occur before and during a stretch

of talk marked as a performance (e.g., when reciting a poem) (Bauman, 1997).

Silence has been studied more or less explicitly in most functionally oriented frameworks of linguistic analysis. Saville-Troike (1985) has offered a holistic view of silence from an ethnographic perspective, arguing that silence in the form of pauses and hesitations carries predominantly affective and connotative meaning, whereas silent communicative acts (such as responses to greetings, queries or requests) may carry propositional meanings on a par with other verbal communicative acts, such as questions, promises, denials, warnings, threats, insults, and so on (*see Speech Acts; Pragmatic Acts; Speech Acts, Literal and Nonliteral*). In Conversation Analysis, pauses have been identified as 'dispreferred seconds' (e.g., Davidson, 1984) such that, if an invitation is followed by a pause, other things being equal, it is most likely going to be interpreted as a 'refusal' (*see Conversation Analysis*). Numerous versions of Critical Discourse Analysis have focused on silence and silencing as forms of sociopolitical control and oppression (Gal, 1989; Theismeyer, 2003) (*see Critical Applied Linguistics*). Other approaches have included semiotics (Kurzon, 1998) and politeness theory (Sifianou, 1997) (*see Politeness*). Many studies have been concerned with crosscultural differences in the use and 'toleration' of silence, including differing attitudes to talk and nontalk, relative length of intra- and interturn pauses, and silence or volubility as sources of miscommunication (e.g., Philips, 1976; Scollon, 1985; Enninger, 1987; Jaworski & Sachdev, 2004) (*see Intercultural Pragmatics and Communication*).

Another productive way of studying silence is by examining specific domains of language use and genres of communication in which silence plays a

prominent communicative or expressive role. These include ritual (including religious) communication (cf. Bauman, 1983), censorship (Jaworski, 1993; Jaworski and Galasiński, 2000), literature and performance art (Tannen, 1990; Jaworski, 1998) (see *Narrativity and Voice; Literary Pragmatics*).

Social Aspects of Pragmatics

K Rajagopalan, State University at Campinas, Campinas, Brazil

© 2006 Elsevier Ltd. All rights reserved.

Introduction

It might seem somewhat strange to talk of 'the social aspects of pragmatics' because the very choice of such a topic might lead a newcomer to the field to think that, strictly speaking, there is nothing social about pragmatics. That such an inference is perfectly

in order may be verified by comparing the expression to an analogous one like 'the economic aspects of the AIDS pandemic' where clearly no one is suggesting that economics is of the very essence as far as AIDS is concerned. Does it at all make sense, one might ask, to conceive of pragmatics in any terms other than social? Alternatively, is it not pleonastic to speak of the social aspects of pragmatics, given that, no matter how you define the field of research called linguistic pragmatics, the social dimension of language will – or should, if it is to remain faithful to

its object of study – turn out to be constitutive of it, rather than something added on to it subsequently, say, by way of an afterthought? As Koyama (1997: 1) put it, “[...] a pragmatic theory is evidently a linguistic and social theory at once.”

Furthermore, if it is granted that pragmatics addresses issues relating to the use of language, as most scholars would agree it does, one might equally wonder how one can sensibly approach such issues except by first recognizing their social embeddedness. Finally, isn't language itself, as Dummett (1975: 135) aptly put it, “something *essentially social*, a practice in which many people engage” (italics added)? Or isn't it essentially “dialogic,” as Bakhtin (1981) forcefully argued, thus, to quote Dentith (1995: 91), “radically socializ[ing]” the way the speaking subject is theorized? Mey (1985: 11) goes straight to the heart of the matter when he says:

We cannot describe language and its use outside the context of that use, viz. the society in which language is used. To start out either with a definition of language (which one?), and then define society (what kind of?), or the other way around, will only lead to endeavors (as frantic as they are makeshift) to paste together what never should have been separated in the first place.

Neglect of Society in Language Studies

But the fact remains that many scholars have traditionally preferred to theorize language in complete disregard for its social setting. There has been a strong tendency among linguists to reify language and view it as a purely mental phenomenon and, as such, the attribute of a single individual existing, as it were, in an idyllically pre-social, Adamic or pre-Fall state. The following remark by Whitney (1827–1894) is typical of a research orientation that dominated most of the thinking on the nature of language in the 19th and 20th centuries.

There can be asked respecting language no other question of a more elementary and at the same time of a more fundamentally important character than this: how is language obtained by us? How does each speaking individual become possessed of his speech? Its true answer involves and determines well-nigh the whole of linguistic philosophy (Whitney, 1875 [1979]: 7).

Notice that the whole emphasis is on the individual acquiring his/her linguistic skills – the initial mention of “us” gives way, with no justification or apology whatsoever, to “each speaking individual” now being considered severally rather than collectively. The fact that, for a language to be said to exist in any minimally meaningful sense of the word there must be at

least two speakers who use that language to communicate to each other, is treated as being of secondary or marginal interest. Instead, all attention is directed at the single individual and his/her knowledge of the language in question. This is all the more intriguing because, as has been pointed out (cf. Andresen, 1990), Whitney belonged to a period in the history of the United States when scholarly research on language was intimately tied to a wider agenda of national self-affirmation, so that, far from being considered an autonomous entity, language was seen as a national symbol, hence approached from an eminently political perspective.

Linguistics and the Focus on the Individual Speaker

In focusing on the individual speaker, Whitney was anticipating what was to become a central tendency in linguistics as the discipline consolidated itself in the first half of the 20th century. When in the mid-1950s, Noam Chomsky revolutionized linguistics with his radically new approach, the centerpiece of his theorizing was, true to this long tradition of relegating the social to the margins, an idealized speaker-hearer, that is to say, the two clearly distinguishable ends of a minimal communicative event (Saussure's twin “talking heads”) fused into one. Society or the social embeddedness of the speaker was, in Chomsky's view, a fact of no great consequence. Here is how he put it: “As for the fact that the rules of language are ‘public rules,’ this is, indeed, a contingent fact.” (Chomsky, 1975: 71). Society is viewed as nothing but the backdrop against which the individual is to be singled out and focused on. The ‘social context’ is then equated with ‘extra-linguistic context’ (Fetzer and Akman, 2002: 395), thus giving short shrift to the fundamental role played by society in constituting a language. Such principled neglect of society has been justified in the name of ‘autonomism’ by Frederick Newmeyer, who summed up the guiding spirit of the whole approach in the following words:

(The advocates of autonomism) approach language as a natural scientist would study a physical phenomenon, that is, by focusing on those of its properties that exist apart from either the beliefs and values of the individual speakers of language or the nature of the society in which the language is spoken (Newmeyer, 1986: 5–6).

Dissident Voices

No doubt, there are important exceptions to the dominant tendency to construct a theory of language around the figure of a single individual. Thus, Hymes warned: “A perspective which treats language

only as an attribute of man leaves language as an attribute of men unintelligible” (Hymes, 1973: 60). Writing in much the same vein, Halliday characterized linguistics as a “social semiotic” and insisted that “[a] speaking man does not talk; men talk” (Halliday, 1974: 17). Outside the disciplinary bounds of linguistics, Wittgenstein (1953) had already put forward what is famously known as the ‘private language argument’: an argument against the very possibility – not empirical, but conceptual – of a language so exclusively private that no one else has access to it. As Itkonen (1996) has forcefully argued, Wittgenstein’s argument strikes at the heart of Chomsky’s conception of language. So, too, from a completely different perspective, the Russian psychologist Lev Vygotskij (1896–1934) had insisted on the importance of social interaction in the development of cognition, arguing that

All the higher functions [including voluntary attention, logical memory, and the formation of concepts] originate as actual relationships between individuals (Vygotsky, 1978: 57).

Speaking from a philosophical perspective, Hacker (1988: 171) preferred not to mince matters when he declared:

The study of language is not a branch of psychology. Little but confusion has stemmed from the supposition that linguists are investigating the nature of the mind, or the mechanisms of understanding.

The Genealogy of the Lone Individual

Given the predominant tendency among linguists to start their inquiry into the nature of language around single speakers and their linguistic competence and only subsequently pan out in order to look at the society of which the individual is an integral part, it is useful to begin by asking why it is that the lone individual occupies such a central place in much of the thinking about language.

The Broader Canvas

It is not all that difficult to track down the origins of modern linguistics’ excessive emphasis on the individual speakers and their linguistic competence, in combination with its relative neglect of society which is where, as we have seen, a language can truly be said to exist. As has been argued by a number of scholars (e.g., Hutton, 1996), modern linguistics is a discipline heavily premised on principles that date back to the 19th century. Taylor (1992: 25ff) points out that,

some time during the 18th century, the idea of man as a socially inscribed being gave way to that of a uniquely constituted self, based on self-awareness and self-reflection. In Germany, Herder (1744–1803) contributed to the shaping of not only an individual identity, but also of a collective one, modeled on that individual identity (for instance, that of a people or *Volk*), by insisting that the Germans could only aspire to a national identity by being true to themselves and their past and not, say, by aping the French.

Ian Watt (1957, 1996) has painstakingly documented the growth of individualism in the 18th through 19th centuries, as reflected in the literary works of the period. The new sense of realism that swept across Europe during that period was accompanied by the equally new spirit of individualism, and the two together underpinned what one might call the cultural and sociopolitical ethos of the period. Daniel Defoe’s *Robinson Crusoe* is a synthesis of that ethos. Modeled on the real life story of a man called Alexander Selkirk, the protagonist of what many literary critics consider the first English novel is the finest example of the glorification of the loner. The importance of *Crusoe* as a key to the understanding of changing perceptions of the lone individual can only be fully appreciated if we compare him to Faust, Don Juan, and Don Quixote, all originally conjured up between the 16th and the 18th centuries by their respective creators as prototypes of ‘anti-individuals’ – the first two are burned in hell-fire and the last is publicly mocked and ridiculed. Incidentally, it is also the very same figure of the loner who is glorified when historians of modern philosophy fondly register that René Descartes, its founding father, experienced a moment of intense inspiration during a dream “in a stove-heated room” when he was serving at Ulm in 1619 (Blackburn, 1994: 100). Linguistics in general and much of early pragmatics is thus wedded to the idea of “the Cartesian autonomous agent” (Kopytko, 2001).

As Watt shows, by the 19th century, this inward-looking and narcissistic individualism had firmly taken hold of the European psyche. The spirit of colonial expansionism that swept across the continent glorified the figure of the loner who braved the elements and conquered distant lands – a Tarzan in the land of apes. The spirit of Enlightenment also took its cue from Descartes and elected the loner as the prototype of the reasoning man in intense meditation, away from the madding crowd, as portrayed in the familiar tale told about Socrates, the Father of Western Philosophy, lost in a philosophical trance while perched on his doorstep before being rudely awakened by a bucketful of cold water tossed at him

by Xanthippe, his notoriously cantankerous wife. Radical, navel-gazing forms of individualism have been complicit in the history of European colonialism (cf. Said, 1978) on the one hand, and, on the other, tied up with the very emergence of modern society (Berman, 1971). It is interesting to note in this context that even Freudian psychoanalysis, which otherwise called into question some of the fundamental tenets of modernism, such as the centrality of the all-knowing rational agent, was built around the concept of the lone individual. In writings such as *Totem and Taboo* and *Civilization and its Discontents*, Freud took a view of the progress of human civilization (as evolving, according to him, from savagery to monotheism and patriarchy) along essentially the same lines as he considered the child's development to adulthood; thus, Freud became the lightning rod for charges of ethnocentrism, and the accusation that the very idea of Oedipus is "colonialism pursued by other means" (Deleuze and Guattari, 1977: 170).

In thinking about and theorizing about language, the intellectual stance adumbrated in the foregoing paragraphs contributed to the consolidation of the idea that language itself is but the visible manifestation of the reasoning mind. It is not surprising therefore that, to the extent that the human linguistic faculty was seen as a property of man's reasoning mind, language itself was seen as primarily pertaining to the individual speaker-listener and only secondarily and derivatively to the society. Indeed, the centrality accorded to the lone individual underwrites the widespread practice among scholars working in the area of language acquisition of simply taking it for granted that phylogeny follows the same course as ontogeny. The underlying principle may be seen as authorizing the widespread use of biological metaphors such as 'growth', 'decline', 'death', etc., to depict specific moments in the history of an irreducibly social object such as language.

The More Immediate Context

The reason why many pragmaticists have tended to concentrate on the cognitive dimension, often to the total neglect of the social – Steven Davis' 1991 book *Pragmatics: a reader* (Davis, 1991) has an entire section devoted to Psychology and Pragmatics but none whatsoever entitled Sociology and Pragmatics) – has more to do with the way this 'branch of linguistics' developed historically, in spite of claims such as made by the editors of the first of issue of the *Journal of Pragmatics* to the effect that the "science of language use," as it is pursued by contemporary researchers, has "no direct ties with the historical use

of the term" (Haberland and Mey, 1977: 1). Originally conceived as part of a general theory of signs, pragmatics is often seen as dealing with those aspects of meaning that cannot be adequately handled by semantics, thus representing, as Tyler (1978: 461) lamented, "a mere appendage of semantics"; alternatively, from the perspective of contemporary generative grammar, pragmatics should be dealt with by syntax, given that a central tendency within this paradigm today is to empty semantics of most or all of its contents, distributing the spoils between the other two components of the old triad (see **Syntax-Pragmatics Interface: Overview**). Katz and Fodor (1963) famously delimited the domain of semantics by stipulating that "Linguistic description minus grammar equals semantics," and Gazdar (1979), most likely taking his cue from them, went on to characterize pragmatics as "meaning minus semantics." In other words, pragmatics became the "wastebasket" (Bar-Hillel, 1971) of linguistics and the working motto of linguists became: "When in trouble call it pragmatics and jump!" (Haberland and Mey, 1977: 7) (see **Pragmatics: Overview**).

The tripartite division of the theory of signs into syntax, semantics, and pragmatics has led many unwitting scholars to conclude that syntax is the crux, or, if you will, the real hard core of linguistics, with a progressive 'softening up' of rigor and internal coherence as one moves from syntax through semantics to pragmatics. This attitude is spelled out in such remarks as

Pragmatics, though less so than syntax and semantics, is characterized by a set of central research issues forming a coherent scientific program of linguistic inquiry (ter Meulen, 1978: 439).

The underlying preoccupation in such descriptions of the role of pragmatics seems to be to define the subfield relative to what by implication is treated as its 'meatier' sister subdisciplines. It is as though the scientific credentials of pragmatics could only be established by parading it alongside the other two members of the triad and conceding how miserably it pales in comparison.

On Defining a New Role for Pragmatics

A more liberating view of what pragmatics should concern itself with is taken by Cook when he says:

Pragmatic philosophy is not, as it is often taken to be, a ready-made technique for analyzing occurring discourse.... The subjective, selective, and fundamentally unscientific nature of analysis of language in context should be acknowledged and not disguised by adopting the symbols and signs of more confident (if less exciting) approaches (Cook, 1990: 15).

In fact, a positive development in recent years has been a clearly discernible tendency among leading pragmatists to rethink the very contribution of pragmatics to an understanding of language. Thus McHoul (1997) makes a clarion call for a ‘pragmamatology’ on the strength of Jacques Derrida’s candid admission that “[g]rammatology has always been a sort of pragmatics” (Derrida, 1988: 159), and urges fellow pragmatists to “‘deconstruct’ all hitherto-existing pragmatics.” Verschueren pleads for a sea-change in the way we conceptualize pragmatics, starting with viewing it as “not a layer or component but a perspective” (Verschueren, 1987, 1999a) and argues that “[a] thorough ‘ideological’ critique of the pragmatic literature is urgently called for” (Verschueren, 1999b: 877).

Mey has been one of the leading scholars in the crusade to openly politicize research in pragmatics, thus initiating what one might refer to as the ‘critical turn’ in contemporary pragmatics. With hindsight, one may consider the following excerpt as marking a watershed:

One of the main theses is that our use of language cements the dominant interests of our society, helping to oppress a large segment of the population (Mey, 1985: 16).

For Mey, work done in linguistic pragmatics should go beyond the merely descriptive or explanatory ambitions of mainstream linguistics and embrace transformative or emancipatory goals. The idea of pragmatics as a ‘perspective of linguistics’ is also forcefully defended by Mey (2001 [1993]).

Not just a perspective *of* linguistics, one may note, but a perspective *on* linguistics. Thus Haberland and Mey (2002: 1672) underscore the urgent need for ensuring that work done in pragmatics is socially relevant, drawing attention to the “society’s need for language studies.” The rhetorical question posed by the authors (Haberland and Mey, 2002: 1673) when they ask whether pragmatics should be defined “from the inside out” or “from the outside in,” “by considering the conditions that make the object possible” may be read as a powerful indictment of the hallowed practice in mainstream linguistics of conceptualizing language by starting with the lone speaker, i.e., starting with what goes on in the mind of the individual speaker and finally paying lip service to the idea that that individual, as it happens, is socially embedded.

The Politics of Pragmatics

The New Orientation

The basic upshot of the discussion in the foregoing section is that research in pragmatics is inescapably

caught up in the politics of language and, no less important, in the politics of linguistics. What the recent about-face in pragmatic research – implied in the transition from a component of to a perspective of/on linguistics – really amounts to is a desire on the part of leading researchers to carve out a disciplinary matrix where they no longer have to wait to work on unresolved problems in so-called ‘hard core linguistics’ (i.e., linguistics where the social question enters as at best an afterthought), but to rethink the very role of society in molding and sustaining language. It is, above all, a desire to free research on language from its time-honored tendency to concentrate on “the language user as an autonomous agent, a kind of linguistic Robinson Crusoe, always reinventing the linguistic wheel” (Mey, 2000: 7).

Interesting Consequences

It is important to point out that a willingness to look at language “from the outside in” rather than “from the inside out” has interesting and often dramatic consequences for the way we identify problems and propose solutions. To begin with, there is a need to recognize that many of the problems we have customarily identified in language are the result of our “inside out” way of conceiving of language. Examples are legion. Consider, for example, the treatment standardly given to the phenomenon linguists have identified as the ‘context.’ The practice of forcibly isolating naturally occurring utterances in order to study them as mere ordered sequences of words or sentences, or what has been referred to as “context-excluding fact fetishism” (Mey, 2003), is what made the whole concept of context so attractive to begin with and at the same time ever so elusive.

Recent work on context and the whole idea of ‘recontextualizing’ in order to solve such problems as ambiguity and vagueness (both of which only exist when sentences are focused on in isolation from their contexts) shows that a radically new approach is called for (Scharfstein, 1989; Akman and Bazzanella, 2003) (*see Context, Communicative*). Nerlich and Clarke (2001) illustrate one interesting possibility of looking at ambiguity, not as a structural given, but as something that language users purposively exploit to certain communicative ends. Contrary to what theorists of implicature and relevance imagine, these authors contend “that people who engage in conversation do not always strive for rationality and relevance, that they do not always intend words to have one meaning and ‘disambiguate’ polysemous words automatically in context” (Nerlich and Clarke, 2002: 1) (*see Conspicuity*).

The Lure of Cognitivism

Although, as we have seen, there is today a clearly recognizable move toward rethinking pragmatics by recognizing the inalienable social nature of language, one should by no means overlook what Haberland and Mey call “a revisionist or reductionist tendency” among certain practitioners, as manifested in the attempts “to revise and ‘redo’ especially Grice and, to a lesser degree Austin” (Haberland and Mey, 2002: 1674).

Perhaps the best-known attempt at ‘revising’ Grice is Sperber and Wilson’s (1986) work on relevance, aptly described by Levinson (1989: 469) as “an ambitious bid for a paradigm-change in pragmatics” whereby “pragmatics is reduced to a single cognitive principle, a mental reflex, which governs much else besides language use.” For Carston (2000: 87), relevance theory brings pragmatics in line with formal linguistics with the only difference that “it is an account of performance mechanisms” (see **Relevance Theory**).

There is no doubt either that Austin, too, has been hijacked to fit into the mold of mainstream linguistics. It has been argued (Rajagopalan, 2000) that Searle’s intervention has been pivotal in ‘domesticating’ Austin and revising his thoughts in such a way that they could be incorporated into the formal structure provided by generative grammar in what is referred to as the ‘abstract performative hypothesis.’ By decontextualizing the individual speech act, i.e., by prying it from its context in order to consider it in isolation as a unit invested with a certain communicative (illocutionary) potential, Searle made it possible for the concept to be smoothly absorbed into the model of syntax being proposed by the advocates of ‘generative semantics’, inviting such pointed criticisms as:

There is, to my mind, no escaping the observation that context, which is most proximately and consequentially temporal and sequential, is not like some penthouse to be added after the structure of action has been built out of constitutive intentional, logical, syntactic, semantic and pragmatic/speech-act-theoretic bricks (Schegloff, 1992: 125).

Societal Pragmatics as a Politically Self-conscious Way of Doing Pragmatics

Margaret Thatcher’s famous words “There is no such thing as society. There are individual men and women, and there are families” (Thatcher, 1987)

were not uttered before an audience of linguists. Yet, her words have important implications for the way we go about setting up priorities in our research in the field of pragmatics. Cognitivism and societalism are not simply two purely theoretical alternatives. Neither is the choice between them simply a matter of attaining adequacy at the descriptive or explanatory levels. The choice between the two is political.

Cognitivism and societalism in pragmatics have their counterparts in political philosophy in individualism and collectivism – which entail conflicting views on the nature of the human being, society, and the relationship between the two. Thatcher’s summary dismissal of society has important political connotations. So, too, does the dominant attitude in many mainstream theories in linguistics of relegating the social underpinnings of language to a lesser status.

Thus Mey and Talbot (1988) criticize what they see as “the presumed lack of social consciousness that is inherent in relevance theory.” “The important bit here,” they note, “is the social anchoring of language use – not, as some would like to have it, the reduction of all society to language use, i.e., to competing discourses.”

Conclusion

As one surveys the recent history of intense research in the field of linguistic pragmatics, one cannot but be struck by the perception that, despite great advances made in the direction of recognizing the social nature of language as the key to coming to grips with language in use, there has also been some rearward maneuvering to suppress the social dimension by privileging the cognitive. The road ahead is thus one paved with political considerations.

Social Class and Status

D F Brown, Howard College, Durban, South Africa

© 2006 Elsevier Ltd. All rights reserved.

The key concepts of social class and status are like most in the social sciences, subject to change in purpose and meaning. Both are rooted in the discipline of sociology, and are central concepts in attempts to describe and explain social inequality and division arising from industrialization, capitalism, and democracy spanning two centuries in industrial and postindustrial societies throughout the world. As to be expected, the major theories differ as to how they define social classes and status groups.

To complicate matters, the concepts of social class and status have been absorbed into linguistic and sociolinguistic theory from different and often conflicting sociological perspectives creating substantial debate. Indeed, some authors would argue that normative sociological concepts have been introduced into linguistic endeavor in an extremely uncritical fashion (Coupland, 2001: 1–26; Williams, 1992; Le Page, 1997).

Since the 1960s, there has been an added interest in the nature of cultural capital, educational credentials, accumulation of knowledge, symbolic systems, and their relationship to social class (Bell, 1974; Habermas, 1987). The investigation of symbolic systems such as language, has in this way contributed to attempts to describe and understand the nature of social class and status. The use of class and status in linguistics, and specifically sociolinguistics, broadens the attempt at understanding society from the socioeconomic base to the super structural and cultural spheres of society. The emergence of sociolinguistics as an area of enquiry coincides with this period.

Common Sense and Class

Social class has its etymological root in the Latin term *classis*, used by census takers to differentiate social strata based on wealth, in order to assess Roman citizens's obligations to military service (Mann, 1983). Within sociological thought, the concept of

social class emerged from common sense concepts. For example, the term 'the working class' emerged in English in the early 1800s to describe anyone who worked for a living, as opposed to landlords, who did not have to work and who had a guaranteed income. It slowly shifted its meaning to people who did mainly physical and skilled labor. The common sense use of class, such as in 'lower class' and 'upper class,' are general and relative terms, not always well defined, and still used as such in sociological and sociolinguistic writing. The terminology of social class is, in other words, not exact and is in need of some explanation if we are to get beyond a common sense notion (Williams, 1983). It is necessary to trace the two 'classical' approaches to social class and status, and then to link them to approaches to research on language and society.

Two Approaches to Class as Social Formation

If defining social class presents problems, it is useful for linguists to know which conceptualization within sociology is being drawn on. 'Class as social formation' refers to the development of class in its dual manifestation. A 'class in itself' encapsulates the objective criterion of the structural emergence of class in relation to the means of production. Once a class develops consciousness and self-awareness as a social group, it becomes a 'class for itself,' as characterized by Marx – the subjective criterion of being a class – and engages with other classes in the furtherance of its own interests. This approach to class as social formation is found in the work of two key theorists in sociology, Karl Marx and Max Weber. These two strands of sociological thought have been elaborated in subsequent generations; their advocates are now described as neo-Marxist and neo-Weberian.

The Marxist Perspective

A Marxist view of social class is based on a subjective notion, with social classes determined by

relationships and consciousness. The early Marxist categories of social class, defined the social groups' relationships to the ownership of the means of production. The key ones were: peasantry (small, largely subsistence farmers), lumpen proletariat (unemployed and criminal strata), proletariat (employed working class), petite bourgeoisie (the middle class) and bourgeoisie (the capitalist class). The relationships were defined by exploitation under capitalism, this entailed the process whereby the bourgeoisie benefited from the surplus created by the proletariat.

The social process surrounding the formation and relationships of these classes was for Marx one of intense conflict and struggle; it was central to determining the course of history. For him, the proletariat was the key to social change, and the class that would ultimately bring freedom from capitalist domination. Hence, his notion that the central social conflict under capitalism was between the proletariat and the bourgeoisie. He discussed other classes but did not portray their role as formative.

This was literally a world-dividing perspective on society. Some within the Marxist tradition were partially critical and wished to modify Marx's arguments. For example, while adopting many of Marx's explanations, members of the Frankfurt school in the 1920s, did not view the working class as a key liberating force. In contrast, they sought to explain its fragmentation on the one hand and on the other, its identity with authoritarian forms of thought in the 20th century (Held, 1980).

Marx had little to say about language and symbolic systems and their relationship to class. For him, these were questions about culture and the superstructure of society. A specifically Marxist perspective on language did not emerge until the 1930s, when the Russian author V. N. Voloshinov wrote his treatise *Marxism and the philosophy of language* (Voloshinov, 1986). This particular work only became generally known in the 1970s through its translation from Russian; written some forty years earlier. It was the first text to look at the relationship between class, semiotic social systems and language from a Marxist perspective. The empirical interest in the text is firstly a stylistic question on the nature of reported speech and then on questions of discourse.

The Weberian Perspective

Max Weber's perspective of class as a social formation differs in important respects. In a key paper, 'Class, status and party,' he added the concepts of status and political party, social groupings that cut across and create social cleavages in social classes. He gave examples of religious and ethnic associations

forming status groups, with strong ties of identity and subjective perceptions of community. Weber redefined the concept of status, and gave it equal importance to class as a motivating feature of conflict and change in society. As a result, the combined power of class, status, and party were what determined historical and social change in an industrializing and bureaucratizing world; social class alone was not the sole determinant for Weber. In addition, he emphasized market and consumption, and saw property or lack of property, as a key to defining class. In the 1920s, Weber saw the future unfolding in what he described as the 'iron cage of capitalism,' the inexorable continuation of class, status group, and party conflicts; and that social mobility was one of the few factors that could temper the consequences of such conflict.

Weber argued that neither class nor status were dominant; instead, he asserted that the one that prevailed at any time depended on economic circumstances. While status group competition predominated during periods of relative stability, class conflict emerged when rapid or extensive economic and technological change took place. From this Weberian perspective, power did not always lie with the dominant social groupings. Social closure, a mechanism for excluding other groups and classes from decision-making positions, was for Weber a means by which status groups or classes organized their conflict.

Both Marxist and Weberian approaches viewed society in terms of conflicting human interests, and held that the nature of class composition, relationships, status, political party, and property constantly changed. (Weber redefined status and added political party and property, and emphasized that power does not always lie with dominant social groupings.) Weber in essence offered a critique of Marx's theory, in that he extended the concept of social class. For linguistics, the significance of social class as a form of stratification involving domination and subordination is that the linguistic and symbolic differences between classes are often readily observed in speech and in communicative practices. The particular perspective that linguists and sociolinguists adopt towards social class will significantly shape how they research language in society.

Neo-Marxists and Neo-Weberians

Contemporary analysis of class has involved a rethink about which groupings are socially significant, and who belongs to which grouping. Neo-Marxist perspectives continue to stress social class as the most significant social cleavage. Neo-Marxists are divided into three groups of theorists: minimalists (Structuralist Marxists), maximalists, and intermediates:

1. The minimalists believe that only manual workers belong to the working class; all other members traditionally thought of as working class are more properly classified in the petite bourgeoisie. Structuralist Marxists such as Louis Althusser and Nicos Poulantzas, held this view (Althusser, 1984; Poulantzas, 1973).
2. The maximalists believe a broad band of the middle class is in fact better classified with the interests of the working class, since they are squeezed by the bourgeoisie to such an extent that their lot is similar to that of workers (a classic position can be found in Baran and Sweezy, 1966).
3. The intermediates believe that many in society fall within a contradictory class location, where their identities and allegiances are insecure and oscillate between classes. No firm social group identity can be forged under such circumstances (Olin Wright, 1985).

First introduced by Weber, the concept of closure, analyses group and class behavior in terms of the exclusion or inclusion of other social groups, and the resulting conflict, was examined by the neo-Weberian writer Frank Parkin, who categorized the workings of social closure as follows: (1) Social closure from below, a subordinate group keeps a dominant group out. (2) Dual social closure, an intermediate group keeps a dominant group and a subordinate group out. (3) Usurpatory social closure, a previously subordinate group comes to dominate and exclude a previously dominant group (Parkin, 1983).

This particular approach using social closure can also be used to link social consciousness and communicative action to class and status, which has particular relevance for the study of sociolinguistics in areas such as code switching (Myers Scotton, 1995).

Table 1 is a brief tabulation (based on Bradley, 1992: 15) of some key contemporary differences between neo-Marxist and neo-Weberian approaches.

Giddens has commented that the various permutations of the meanings of social class bring neo-Weberian and neo-Marxist understandings of class very close together at times. For example, the understanding of social mobility is difficult to distinguish from 'contradictory class location,' where people appear to occupy an intermediary position and switch their allegiances and identities between classes (Giddens, 1993).

Class as Category

In stark contract to the idea of class as social formation, class as category presents a consensual, normative view of society. This idea of class has an affinity with Émile

Table 1 Comparing Neo-Marxists with the Neo-Weberians

<i>Neo-Marxist</i>	<i>Neo-Weberian</i>
1. Class divisions generated by relations of production	1. Class divisions generated by operation of market
2. Classes unified by exploitation	2. Classes fragmented by markets
3. Conflict between classes dominates social relationships	3. Conflict within classes as important as conflict between them
4. Middle class linked to one of major classes	4. Middle classes are autonomous groupings as significant as the propertied and working classes
5. Consciousness arises from relations of production	5. Consciousness has many different sources

(Based on Bradley, 1992: 15).

Durkheim's structuralist interpretation of the division of labor in any society, but specifically industrial society, and the structural analysis of all social institutions in relation to their social functions within society. Durkheim was interested in the basis of social order and the establishment of social norms, rather than conflict. By the 1950s, structuralism had a far-reaching impact on social thought, even influencing Marxism. Most importantly, it spawned the structural functionalism and normative sociology of Talcott Parsons in the United States (Parsons, 1964).

The approach of defining class as category, brings us somewhat closer to the original Latin meaning *classis*. By measuring income levels or classifying people into occupations, one can determine social class. This is a socioeconomic definition of class, with no reference to subjective notions of consciousness of class position and status. It is referred to as a 'scale and category' measurement of social hierarchy, which tends to permeate a bureaucratic understanding of social hierarchy. It is a form of measurement that has been used, for example, to determine actuarial predictions of life expectancy and insurance risk, and to analyze potential markets. As a gradational measurement, it is well suited to quantitative empirical investigations of society.

The structural functionalist perspective of Talcott Parsons was the dominant postwar voice in American social theory. Parsons claimed the influence of Weber, whom he encountered as a student, and whose work he translated and published. Yet, he adopted a normative, consensual approach to social structure, and largely used the perspective of social class as an occupational role. This body of social theory emphasizes the possibility of social mobility, and has used the version of

industrial democracy as developed in the United States, as its social exemplar of advanced social development. It has been influential as a framework in sociolinguistic studies, particularly in understanding of the relationship between language and social class, since variables such as income, occupation and educational level are all deployed in understanding the normative category of class. An example is William Labov's use of occupational hierarchy to assess class speech variation in his survey of New York City (Labov, 1966).

The Use of Class and Status in Sociolinguistic Research

Class, Codes and Control

Bernstein's seminal work, *Class, codes and control* was one of the first systematic attempts to investigate the cultural features of social class and its relationship to education. His concept of code, is in essence, a communication process deeply embedded in the nature of social stratification. It is not readily evident, and has therefore to be subjected to decodification and analysis in order to be rendered explicit. Drawing on the work of Marx, Weber, and Durkheim, Bernstein looked for reasons for the perpetuation of working class failure in the educational system; his research typified the turn to cultural and superstructural analysis of social inequality.

His research in 1960s Britain consisted of a relatively homogeneous social context, with very small minority populations. As in many European societies at the time, the articulation of class interest and conflict was well reflected in the major competing political parties. Bernstein's belief was that the reproduction of working class failure in the face of post-war educational reforms could in fact be understood and rectified. He developed Durkheim's profiles of the working class and middle class family, and typified their communicative codes as 'mechanical' in the case of working class (an understood, implied process of communication with much left unspoken), and 'organic' in the case of the middle class (a more explicit negotiation of social meaning). In turn, he investigated the structure and process of communication within the schooling system, and the congruence or lack of congruence between the school and the family. He sought to establish patterns in communication and socialization that disposed the middle class to success in educational contexts.

Bernstein developed the notion of 'elaborated' and 'restricted' codes, the working class had a restricted code and the middle class an elaborated one. Code, in fact, referred to a great deal more than the surface features of morphology and syntax.

Unfortunately for Bernstein, this was the feature that became synonymous with the so-called 'deficit hypothesis.'

In what was a voluminous work based on the contributions of many researchers, one Bernstein article dealt with grammatical and semantic structure and linked this, in a strong expression of the Whorfian hypothesis, to the concept of working class language being in itself cognitively deficient. It described the features of a restricted code at a syntactic and morphological level, which was thought to inhibit communication and conflict with the communicative systems in education, in contrast to the middle class elaborate and explicit code, which enhanced this process. This was in turn thought to create problems in the communicative adaptation to schooling for working class children.

This aspect of the research became enlarged and was misconstrued as the substance of Bernstein's work. In fact, as argued above, many of the features of Bernstein's analysis of the working class family drew on structuralism, and were concerned with processes of communication, which had nothing to do with surface features of language and even contradicted their importance (Atkinson, 1985). Yet, many subsequent research works repeatedly drew attention to the surface levels of working class speech, and claimed that specific means of expression were deficient and at odds with institutional forms of communication. It was also this feature of the research that made it extremely significant to linguistic and sociolinguistic discussion.

This small aspect of Bernstein's work was taken up in the educational reformism of the 1960s in the United States by a project called Operation Head Start (Bereiter and Engelman, 1966). This project advocated the teaching of standard grammar as the solution to educational failure in the black ghettos. Drills were developed for the development of standard speech varieties; the result was to further alienate the communities from the schooling process.

The result was the celebrated but unfortunately one-dimensional critique of Bernstein developed by William Labov in support of the logic of nonstandard English of African-Americans, the key target of educational reform at the time. The implied acceptance of the strong version of the Whorfian hypothesis in Bernstein's work was the basis for the critique. Labov demonstrated very adequately how surface features and sociolect had nothing to do with rational thought and established, in contrast, the difference hypothesis (Labov, 1966). This much-remembered debate, in many ways, was built on straw characterizations of each side of the argument.

Bernstein did not anticipate that his work would be used in the context of a minority status group along with a prejudiced perception of the group's speech patterns. He did not expect the degree of misconstrued interpretations of his work in the United Kingdom. Any validity on the sociological side of Bernstein's research was muted in the face of the barrage of criticism that was directed against what was perceived to be a restatement of class prejudice in his work.

There were in essence many more concerns in Bernstein's research, not least of which was the acquisition of literacy, the graphic shibboleth of all educational systems. The linguist Halliday defended Bernstein's work and qualified his understanding of it, on the basis that it was concerned with questions of literacy, and creative work in educational practice. As Bernstein himself pointed out, "We are told and socialized into what to reject, but rarely told how to create (Bernstein, 1977: 167)." Much was produced in the concern for language across the curriculum, and the methods of teaching reading and writing that emerged from this period of critical debate about language teaching and the development of literacy in the United Kingdom at the time (Hasan, 1996: 34; Halliday, 1978). The debate over restricted and elaborated codes and its tenor probably lost more ground for sociolinguistic enquiry than it gained.

Bernstein continued to look at notions of horizontal and vertical knowledge and issues that are of central concern to sociology in more recent times. Bernstein's death in 2000 led to a great deal of revisiting of his work (Moore and Muller, 2002: 627).

Variation Studies and Class as Category

A number of large-scale quantitative studies on language variation were conducted in the 1960s and 1970s, by researchers such as Trudgill in the United Kingdom and Labov in the United States (Trudgill, 1974; Labov, 1966). These studies were symptomatic of the nature of quantitative social enquiry at the time, but their important common feature was that they focused on socioeconomic and stylistic stratification of linguistic variables over large populations. This approach adopted a consensual view of language and social class; that is, class as category, as outlined above. For a period, these approaches sought to define linguistic and sociolinguistic research endeavor as having scientific validity.

Labov's work is interesting in that it applies a very clearly developed category approach to class. The categories he used in his survey of New York City in 1966 are shown in Table 2 (from Eckert, 2000: 26).

This research is very much part of the investigation of cultural phenomena and their relationship to class,

Table 2 Labov's class categories

Category	Description
Upper class	First rate professional, manager, official, or proprietor of a large business
Upper middle class	Career man in professions, managerial, official, or large business positions
Lower middle class	Semiprofessional, petty businessmen, white collar, foreman, and craftsman
Working class operatives	Blue collar workers dependent on labour market
Lower class	Laborers with insecure job status

(In Eckert, 2000: 26).

which has been typical of the postindustrial research endeavor, particularly in advanced industrial societies. The consensual nature of this form of social investigation is criticized for failing to portray the dynamic nature of social change and innovation necessary for social explanation. What Labov produced with this research was a series of functionally explained categories, where occupation was seen as the very basis of class, and the agent of language change. For him, it proved the plasticity of the vernacular and the endurance of the standard variety.

His identification of the linguistic insecurity in the lower middle class, and the desire for hypercorrection on both a class basis and a gender basis, is interesting for its depiction of class semiotic and its interface with a status group such as gender. Little is made of the social groupings and networks in the construction of the standard and vernacular that Labov portrays on his linguistic scale: the interpretation of different styles and relation to social class is limited.

Labov's former student, Penelope Eckert, has completed an interesting reinterpretation, using a Bourdieu-like analysis of the networks that sustain standard and vernacular forms. She shows the significance of past and present variation studies for current social description and understanding of the nature of social class and status (Eckert, 2000: 16). Her work represents an ongoing debate with Labov, which makes the latter's work as pertinent today as Bernstein's.

Bourdieu's Cultural Capital, Linguistic and Symbolic Markets

Pierre Bourdieu is perhaps the strongest voice in sociological writings, other than Bernstein, to have rearticulated the question of culture and its meaning in the stratification of society. He has developed the concepts of 'cultural capital,' 'fields,' and 'habitus.' Cultural capital is the value placed on an aspect of culture; a field is an area of endeavor, such as education; and a habitus is 'embodied social structures that serve as principles organizing practice.' His

work has permeated the field of sociolinguistics since his first essays on the linguistic market on the value of the symbolic system to the accumulation of cultural capital. His work has been highly influential.

Class codes, unlike Bernstein's elaborated and restricted, are simply described by Bourdieu and his associate Passeron in terms of 'bourgeois,' and 'common' parlance. A Latinate vocabulary and a striving for novel expressions mark bourgeois parlance. Common parlance is characterized by situational reliance, non-learned vocabulary, and reliance upon shared figures of speech (Bourdieu and Passeron, 1977: 116). The bourgeois code is fostered in the educational system, and where the dominant language is also the official language. The privileged, through their command of a bourgeois code, are better able to cope with the demands of the education system. Those students who possess common parlance cannot develop an understanding of what might be expected of them in such a field. Bourdieu, unlike Bernstein, did not express any hope for educational reform through remediation, as he treated the schooling system as one that systematically served the interests of class-divided societies.

For Bourdieu, the concept of linguistic capital is but one dimension of the concept of cultural capital. Language use is valued in different domains. The state, Bourdieu argues, unifies the linguistic market. He asserts that the school-based standard language underpins the requirements of a literate class, in which text falsely corresponds with truth and social domination is represented falsely as mental development.

As influential as Bourdieu's work has been, it has also attracted criticism. Collins argues that the determinist nature of class in his work is not able to deal with both structure and agency/practice in understanding the subjective conditions of dominated groups (Collins, 1993: 121–123). It is this balance between structure and agency in understanding social class that Giddens has termed 'structuration' (Giddens, 1979). Eckert has also drawn on this more complex concept of social class and its social determinants in her work (Eckert, 2000: 44).

Sociolinguistics is concerned with sociological explanations of the semiotic system. According to Eckert, a social theory of language cannot view *langue* as a given, but must be about the process of being conventional. What the creolist Le Page claims is needed is to understand how languages are 'named, formalized, standardized and totemized by society' (Le Page, 1997: 32). The ideas of ideal speaker and listener, and the dichotomy of competence and performance, are abstractions that are meaningful only in the context of showing us the nature of domination and subordination in understanding language and society. In this regard, Bourdieu is not alone in going

to the root of questioning the very concept of 'a language' in order to provide it with an adequate sociological explanation (Bourdieu, 1992: 43–65).

Social Network and Social Class

Milroy and Milroy argue that the concept of being 'local,' or district-based is strongest amongst working class communities. They build on the arguments of Thomas Højrup, who found that working class communities are more fragmented than others, and developed a concept known as a 'life mode' analysis, to construct a model that examines cultural aspects of social existence. In their research in Belfast, Milroy and Milroy traced the existence of close-knit networks that served as the basis for vitality of the vernacular forms of working class language. Williams has criticized this perspective as being a rejection of sociological analysis, on the grounds that network theory is incompatible with social class. Le Page defends the Milroy network research, by claiming that their network theory is both compatible with social class analysis and a useful tool to explore working class solidarity and linguistic identity (Milroy and Milroy, 1997: 61; Le Page, 1997; Højrup, 1983). This technique for exploring language change and understanding the manifestations of class and status has been followed in a number of studies (Le Page, 1997; Williams, 1992).

Sociolinguists have sometimes naively deployed the concepts of class and status on the supposition that 'language mirrors society.' The relationship is rather more complex. Class and status are not fixed notions in sociology and have been interpreted very differently, as has been seen. Sociology and social theory are now moving beyond the characterization of the societies we live in as 'postindustrial,' and now look to the notion of the transition in capitalism to 'the iron cage of the information age,' and the rise of the network society and the rapidly changing nature of local social class and status groups globally (Castells, 1996). The implications for the understanding of language in society are enormous, the way forward is to maintain close but critical links between the ideas of social class, social status, and sociolinguistic theory.

Social-Cognitive Basis of Language Development

M Tomasello, Max Planck Institute, Leipzig, Germany

© 2006 Elsevier Ltd. All rights reserved.

Linguistic communication is a form of social interaction. It is a special form because it is mediated by linguistic symbols. Linguistic symbols are social

conventions used by human beings to direct one another's attention to various aspects of their shared environment. Different societies have created different sets of linguistic symbols – at the moment there are approximately 6000 languages in the world – and indeed the linguistic symbols of each society evolve fairly rapidly over historical time as speakers modify

existing ways of talking to meet changing communicative circumstances.

Children are exposed to the linguistic conventions of their speech community as they interact socially with mature language users. To acquire productive use of linguistic conventions children must have the social-cognitive skills to:

- participate with others in the joint attentional interactions that provide a common referential ground for symbolic communication (joint attention);
- understand the communicative intentions of others as embodied in linguistic symbols of various types (intention reading);
- take the perspective of others in tailoring the choice of linguistic expression to particular communicative contexts (perspective taking);
- collaborate with others in coconstructing a conversation with a shared topic and ‘relevant’ contributions of new information (communicative collaboration).

Other animal species do not possess any of these social-cognitive skills – at least not in their human form – and that is the main reason why they are unable to create or to learn a human language (Tomasello, 1999, 2003).

Joint Attention, Intention Reading, and Word Learning

The social-cognitive foundations for language acquisition begin to emerge in human ontogeny near the end of the first year of life in various of infants’ nonlinguistic activities. Most importantly, at around 9 months of age infants begin to interact with other people triadically around a ‘topic’ of mutual interest (‘the primordial sharing situation’). Thus, they begin to follow others’ attention to external events and entities (Tomasello, 1995), to direct others’ attention to external events and entities using nonlinguistic gestures for both imperative and declarative purposes (Bates, 1979), and to engage with others in relatively extended bouts of joint attentional activity (Bakeman and Adamson, 1984). Other animal species engage rarely, if at all, in triadic communicative interaction.

Children acquire their earliest linguistic conventions within the context of routine joint attentional activities such as having a meal together, taking a bath together, going for a ride together in the car, and so forth (Bruner, 1983). These routines serve as necessary scaffolding because linguistic symbols are associated with their communicative functions only conventionally – which presents a unique learning situation. That is, no matter how intelligent a child

is, she cannot on her own figure out what some sound means, but rather she must experience a speaker using that sound for the purposes of communication and then determine why, toward what communicative end, he is using it. This determination requires the child to have some nonlinguistic access to the kinds of thing the adult may be communicating about. This is provided by the joint attentional activity, which basically defines ‘what we are doing’ and so determines a kind of domain of relevance. For example, if a child hears the new word *gavagai* from an adult out of the blue, so to speak, she will not learn it because she has no idea why, for what communicative purpose, the adult is using this word. But if she and the adult are giving her a bath together and the adult looks at the rising water level and says *gavagai* while turning the faucet off, there are only a limited number of plausible meanings for this expression – assuming it is relevant to the activity. It is thus not surprising that Carpenter *et al.* (1998) found that the size of children’s early vocabularies is highly correlated with the amount of time they spend in joint attentional engagement with others.

For the child to be able to zero in on a single one of the plausible meanings of a new expression used within a joint attentional activity, she must be able to read the communicative intentions of other people more specifically; that is, she must be able to determine specifically what the adult intends for her to attend to. Initially, it is very helpful if adults do most of the work and follow into the child’s already existing focus of attention when using a new expression (see Tomasello, 1988 for a review). But as development proceeds, children become ever more skillful at determining adult communicative intentions in novel contexts in which the two of them are focused on different things. Thus, if an adult uses a novel word when he, the adult, is attending to one object and the child is attending to a different object, the 18-month-old child will follow the adult’s attention to the object on which he is focused in determining the intended referent (Baldwin, 1993). Further, if the adult is picking his way through a toy box full of objects in search of a ‘modi,’ 18-month-old children will be able to pick out his intended referent by the fact that he rejects some objects and finally accepts one – despite the fact that he looks equally at them all. And if the adult uses a novel verb to announce an intended action (“Now, let’s dack Ernie”) and then performs one act on purpose and another by accident on Ernie – with different orders of these two across children – 24-month-old children know that the intended referent of *dack* is the one done on purpose (see Tomasello, 2001 for a review of these and similar studies).

Children's acquisition of linguistic symbols thus depends most fundamentally on their ability to participate in the joint attentional activities that create a common communicative ground with their interlocutor and on their ability to read the intentions of others in particular communicative contexts.

Perspective Taking and Construction Learning

The broader social purposes for which people use language are such things as greeting others, informing others, asking questions, requesting favors, and so forth. In many cases the speakers of a language have conventionalized entire grammatical constructions for the most frequently occurring of these functions, for example, English *wh*-questions for requesting information and imperatives for requesting favors. In addition, speakers use different conventionalized grammatical constructions depending on who the listener is and what she knows and expects. For example, if we are conversing about my sister and I want to tell you something that happened to her, I might very well use an English passive construction such as *She was sued by her landlord*. Or perhaps I learn that you erroneously believe that my sister's therapist sued her, in which case I might correct you by using a cleft construction such as *It was her landlord that sued her*. If we have been talking about something else I might introduce the topic by using some kind of presentational construction like *You know my sister's landlord, he . . .*. In theories of language such as cognitive linguistics and construction grammar these kinds of constructions are, like words, linguistic symbols that pair a linguistic form and communicative function (i.e., the communicative intentions the symbol embodies). Children thus learn these constructions in a way that is not totally different from the way they learn words, that is, by observing people use them for particular communicative functions – which they determine by intention reading, including the subintentions of any subconstructions involved (e.g., noun phrases, locative phrases; see Langacker, 1987; Goldberg, 1995).

From a social-cognitive point of view, the most interesting thing about the acquisition of constructions is that children must learn when to use which one, and this often involves a subtle assessment of the knowledge and expectations of the listener. For instance, in their acquisition of noun phrases 2-year-old children learn to do such things as use pronouns to refer to an entity when they are jointly attending to that entity with their listener, but use a lexical noun with a determiner (or even a relative clause) when the two of them are not jointly attending (see Tomasello,

2003; Chap. 6 for a review). Similarly, to learn to use a cleft construction (e.g., *It was Jeffrey that took the cookies*) children must be able to tell that their listener is currently under the mistaken impression that someone else took the cookies and then choose a construction that makes contact both with the mistaken impression and its correction. Saying *The vase broke* enters the event from the perspective of the vase whereas saying *I broke the vase* enters it from the perspective of me and my activity (Budwig, 2000).

In all these cases, then, children must learn the perspective, in the broad sense of that term, that a construction embodies, and the communicative situations in which it is appropriately used. They do this initially in a very local and item-based way. For example, they might initially be able to alternate between the object's and the actor's perspectives only with the verb *break*, with extension to other verbs coming only very gradually (Tomasello, 2000).

Communicative Collaboration in Conversation

As children are acquiring the various symbols and constructions of their language they are at the same time learning how to use these symbols and constructions to communicate more effectively in extended conversational interactions with other people. Conversational and discourse skills are concerned not so much with the mastery of the grammaticized and conventional aspects of a language, but more with the mastery of strategies for using those constructions effectively to manage the flow of information across turns in a developing conversational interaction. Skill at conversation involves such things as taking turns appropriately, managing the conversational topic effectively, and repairing a conversational interaction when it breaks down.

Becoming a skilled conversationalist requires children to read the intentions and take the perspective and role of their listener in many complex ways in novel contexts, and so many conversational skills do not fully develop until late in the preschool period. Thus, at 2 years of age only a minority of children's utterances are semantically contingent on the adult's previous utterance, and very few of their turns include reference to both the preceding topic and also some new information – the prototype of a mature conversational turn. When they do engage in a relatively extended conversation on a single topic, 2-year-olds typically take only one or two turns per conversation, with this value doubling by about 4 years of age (Pan and Snow, 1999).

Conversation is a form of collaboration in the sense that from a very early age there is a 'negotiation

of meaning' between the two conversationalists (Golinkoff, 1983), and there are requests for clarification back and forth when one person does not understand something in the other's formulation. Almost from the beginning of the language acquisition process, young children both respond to requests for clarification and, less frequently, request clarification of others in their conversations (see Tomasello, 2003: Chap. 7 for a review). This again requires sophisticated skills of intention reading and perspective taking.

Collaborative activities, either nonlinguistic or linguistic, thus require participants to have a common goal and to work together in coordinated ways to achieve it. This coordination is not a foregone conclusion, and indeed animals that communicate with one another in fairly sophisticated nonsymbolic ways still do not engage in the back and forth of conversational interaction (and often engage very little in collaborative, turn-taking interactions of any kind).

Conclusion

Children thus employ their species-unique social-cognitive skills to acquire and use a natural language – skills of joint attention, intention reading, perspective taking, and communicative collaboration. But in the process of acquiring a language, children are led to consider various particular intentions and perspectives that they almost certainly would not have created on their own: the very same animal is referred to on different occasions as a dog, an animal, a pet, or a pest; the very same action is referred to as running, fleeing, chasing, or exercising. Acquiring a natural language in interaction with other persons thus leads young children to create some species-unique forms of cognitive representation, namely, perspectival cognitive representations (Tomasello, 1999).

A number of theorists have also proposed that conversation and discourse might play an important role in children coming to have a 'theory of mind,' that is, in coming to view other persons as mental agents who can have beliefs (including false beliefs) about the world (Harris, 1996). Thus, to engage in true conversation children must in some sense simulate the perspective of other people as they express themselves linguistically, and thus the back and forth of discourse involves the child in a constant shifting of perspectives from her own to that of others and back again – which helps her to construct both social norms and individual attitudes and beliefs (Tomasello and Rakoczy, 2003).

And so the relationship between children's social cognition and language is not one way. They must have certain social-cognitive skills to acquire a language, but then engaging in linguistic communication

leads them to create new social-cognitive skills. Acquiring a language may thus be seen as another manifestation of the basic dialectic in which children are biologically prepared for culture, but then participation in culture – whose artifacts embody the skills, attitudes, and perspectives of other individuals – takes their cognitive skills to new places.

Socialization

J Cromdal, Linköping University, Linköping, Sweden

In anthropology, sociology, as well as social psychology, studies of children are traditionally found under the heading of 'socialization.' In the widest sense, this term refers to an indefinite array of social events taking place in ordinary life surroundings as well as in institutional settings, representing events through which people become skilled in the ways of society. However, researchers within the social and behavioral sciences have settled for a much narrower conceptualization, typically treating socialization as the process through which adults secure the transition of the youngest generation from childhood into ordinary membership of society.

For the early sociologists such as Durkheim and Parsons, who conceived of society largely in moral terms, socialization is primarily a matter of the individual internalizing a set of norms and values crucially shared by members of society. For sociologists and psychologists alike, socialization is the process through which the individual acquires a sense of a social 'self.' Within traditional social anthropology (e.g., Mead, 1930), this process is taken to also include the development of particular skills in relation to the socioeconomic order of a culture. Thus, the notion of socialization has provided sociologists and anthropologists with a way of accounting for the maintenance and reproduction of social order, and furnished psychologists with an axiomatic for understanding the individual's social as well as moral development (Tholander and Cromdal, 2005).

Norms, Rules, and the Maintenance of Social Order

One of the central tasks of early sociology was to explain how societies are held together. Assuming that humans are born into society as virtually asocial beings, Durkheim (1979) came to the realization that the notion of mutual economic interdependence, with

its resulting division of labor among members of society, is not enough to account for the maintenance and reproduction of social order. For society to be possible, there must be an underlying consensus among its members concerning the most central values and beliefs that inform and crucially constrain social behavior. This assumption raised questions about how society's central norms and values are transmitted across generations, how in becoming part of society, children come to internalize these most central features of social life. For Durkheim, this task is handled by society's institutions: the family, the church and most importantly the school, which is responsible for the moral education of the child. (see **Institutional Talk**).

Following up on these ideas, Parsons (1951) sought to elaborate how societal norms and values are translated into concrete rules of behavior, i.e., how they inform and essentially govern people's actions. Central in his work is the notion of 'value orientation patterns,' which allow individuals to infer the expected forms of behavior from the social roles participants occupy in a variety of settings. This allows people not only to recognize what is expected of them when acting within their roles but also to assess other people's role performance. This is a crucial aspect of the normative nature of social structures, as it enables society's actors to impose social control on each other. Moreover, it allows adult members of society to socialize the children. In this way, the processes of social control and socialization operate within the social system toward an ideal state of equilibrium.

A Developmental Orientation

A notable feature of these early works as well as their subsequent applications is that the concept of socialization is almost exclusively applied to the study of children. In his work on society as a social system, Parsons readily acknowledged that socialization is a life-long process, only to argue later on the same page that sociological inquiry should remain focused on

childhood, or the period of 'primary socialization.' It is during this period in life, Parsons argued, that the 'major value-orientation patterns,' comprising normative patterns of behavior, are 'laid down' with in the social actor (Parsons, 1951: 208). These orientations to shared values were seen as foundational to an individual's 'basic personality structure,' and as such they would not undergo substantial change later in life. Among the specific processes of socialization, Parsons identifies such mechanisms as *reward-punishment*, *instruction*, and a set of *mechanisms of value-acquisition*, of which the most important one is the child's *identification* with the adult.

Parsons's integration of various streams of concurrent psychological reasoning within his systemic theory of society suggests that socialization theory is not a strictly sociological enterprise. Indeed, it provides something of a paradigmatic perspective for social and behavioral studies of children. Hence, issues of socialization have been addressed by virtually all the major psychological theories of development, and there are few major works within social anthropology that do not attend to the problem of cultural transmission across generations, often referred to as 'enculturation.' Common to all the traditional – and much of the contemporary – socialization research is a view of childhood as a period of transition, during which children gradually become (or fail to become) full-fledged members of society. In this way, socialization research trades on massively commonsensical and normative notions of children and childhood. At the same time, it provides a scientific foundation for these cultural beliefs.

Socialization: Critical Perspectives

One of the earliest criticisms of socialization theory appeared in Wrong's (1961) essay on the 'oversocialized conception of man,' in which he argues that the notion of socialization is used as an automatic account for any queries of social order:– Why does society hold together? – Because people are socialized to follow common rules of behavior. The problem here, according to Wrong, is the implication that, having been socialized into society, people have little choice but to follow its rules. Apart from its social determinism, this view renders sociological inquiry trivial.

Similar problems were addressed in Garfinkel's early ethnomethodological investigations (1967), in which he points out that sociological theory construes the member of society as a 'judgmental dope,' who 'produces the stable features of the society by acting in compliance with preestablished and legiti-

mate alternatives of action that the common culture provides' (Garfinkel, 1967: 68). Garfinkel then proposes that in billing the member of society as a judgmental dope, social science scholars employ a variety of (research) procedures, designed to preclude the practical concerns of members in actual social situations. The concept of socialization can then be seen as an analytical resource to this end, in that it allows researchers to gloss over (Mackay, 1975), rather than investigate, the lived features of cultural (re)production. Indeed, the invisibility of actual practices of socialization is already built into Parson's sociological theory, in which he proposes that 'many features of the actual process of socialization of the child are obscure' (Parsons, 1951: 214).

A related set of problems in socialization theory pertains to the specific status of the child as social actor, including, as we have noted, a general research bias toward issues of development. As Speier (1971: 188) points out:

sociologists (and this probably goes for anthropologists and psychologists) commonly treat childhood as a stage of life that builds preparatory mechanisms into the child's behavior so that he is gradually equipped with the competence to participate in the everyday activities of his cultural partners, and eventually as a bona fide adult member himself.

Speier refers to this view as the 'classical' formulation of socialization because, although employed by researchers for 'scientific' purposes, it is rooted in folk beliefs about children. These beliefs form a set of ideological conventions, according to which children are treated as incomplete social participants, as 'incipient beings' (Durkheim, 1979). On this view, children's social skills are thought of in terms of incompetence, or at best, pre-competence, and therefore, children need to be guided into social life by adults.

Jenks (1997) proposes that most social theories adopt this adult-oriented perspective on children and therefore 'spectacularly fail to constitute the child as an ontology in its own right' (Jenks, 1997: 10). We should note that the adult perspective not only casts children as less-than-competent participants in society's business but also ascribes the problem of participation in social life *to the child* (Speier, 1976). One important implication of this interpretive imposition is that children's actions will be understood in ways that conform to, ratify and elaborate the biased, adult-folklore-oriented view of what goes on between children and adults. This in turn inevitably precludes not only any adequate understanding of children's social worlds but also inhibits an understanding of the joint interactional work in which both parties to adult-child exchanges must necessarily

engage. Ironically, it is precisely these situated practices of action and reasoning that form the very basis of socialization (see Edwards, 1995, and Waksler, 1991, for further discussions).

These concerns led Speier (1971) to respecify the very notion of socialization as above all a matter of developing skills for participation in social events. This opens up for empirical investigation of socialization from within social events, by attending to the organization of talk-in-interaction. In this vein, pioneering ethnomethodological works by Sacks (1992, Vol. 1, Lecture 2, Spring 1966: *et passim*), Speier (1976), and Mackay (1975) demonstrate how children manage to participate in talk under overwhelmingly restricted conversational rights with adults. (see Sacks, Harvey.) In later years, analysts of social interaction have focused on the organization of talk within a range of activities within the peer group such as negotiations of local alignments and friendship relations (Goodwin, 1990; Whalen, 1995), teasing (Tholander, 2002), and the management of conflict (Cromdal, 2004; Maynard, 1985). (see **Organizational Speech; Institutional Talk.**)

The focus on socialization within the peer group arose out of an increasing sociological interest in children's play. As Sutton-Smith pointed out, "Peer interaction is not a preparation for life. It is life itself" (1982: 75). In this vein, interpretive sociologists and social psychologists argued that it is through the management of peer group concerns that children appropriate the values and beliefs of the adult world, and it is through these necessarily communicative practices that children produce their own unique peer culture (e.g., Corsaro and Eder, 1995; Harris, 1995).

The necessity of studying the communicative practices within the peer group is also highlighted by language-oriented ethnographers, who not only demonstrate how children are socialized through language but, crucially, demonstrate how the children are socialized to use language appropriately within distinct social groups (e.g., Ochs and Schieffelin, 1995). These studies, commonly known as 'language socialization,' provide a critical perspective on the relation among language, culture, and communicative practice, and its role in children's language acquisition.

In 1990, James and Prout outlined a social constructionist framework for the study of children and childhood. This interdisciplinary enterprise was designed to revitalize and redefine the status of childhood on the social studies research agenda, and was accordingly launched as a 'new paradigm for the study of childhood' (James and Prout, 1990: 5). Echoing the early ethnomethodological critique, research-

ers embracing this orientation strongly dispute the traditional view that studies of childhood are interesting only insofar as they tell us something about future adulthood, along with its allied notion of children as passive recipients of culture. Instead, within this approach – sometimes referred to as 'the new social studies of childhood' – researchers insist that children be recognized as social agents, capable of constructing their own social worlds. A further interest is in understanding the relations between children's social worlds and society's institutions, such as the family, school, or any other of the adult-dominated spheres of social life in which children routinely participate. Stressing the constructed nature of cultural conceptions of children and childhood, researchers clearly recognize that this process of construction is part and parcel of everyday interactional practices. However, although James and Prout emphasize the need for empirical studies to equal the theoretical development of this enterprise, analyses of situated interactions through which children create their peer cultures within society have hitherto been scarce. Hence, the current challenge for studies of children and childhood lies in exploring the overwhelmingly language saturated practices through which children take part in society's business.

Socialization: Second Language

Second Language Socialization

Socialization refers to the interactional processes through which a child or other novice develops the competence required for participation in the social life of a particular community or communities, including routine cultural practices, such as language and literacy activities, and local preferences for action, thought, and emotion. These processes occur in large part through language, the primary symbolic medium of cultural reproduction and transformation. Language socialization researchers invoke Whorfian views of linguistic relativity in articulating the view that “acquiring a language is part of a much larger process of becoming a person in society” (Ochs, 2002: 106). Accordingly, the language socialization paradigm is concerned with two interconnected phenomena: how children and other novices are socialized to use language and how these same individuals are socialized through the use of language. Language socialization research strives to relate individual processes to broader sociocultural contexts, seeking a maximally holistic perspective while simultaneously attending to the microlevel details of language use.

Background and Key Concepts

Originally articulated nearly two decades ago (Ochs and Schieffelin, 1984), this paradigm has retained an emphasis on the dialectic of language learning and socialization. Early language socialization research emerged as a branch of linguistic anthropology, opening new analytic pathways, through the combined use of ethnography and microlinguistic analysis, toward an understanding of first language and literacy development in childhood. Focusing on young children acquiring their L1 in diverse sociocultural settings (Ochs, 1988; Schieffelin and Ochs, 1986), and on relationships between culturally specific patterns of language socialization at home and in school (e.g., Heath, 1983), this research clearly documented the cultural specificity of language and literacy socialization practices and their developmental consequences during the transition from home-based to schooled activities. In subsequent years, language socialization research has expanded beyond its original emphasis on first language learning in childhood, incorporating studies of second and multiple language learning across the life span.

Inspiration for the genesis of the approach is often traced to seminal work on interactional and communicative competence by Gumperz (1982) and Hymes (1972), especially Hymes' formulation of the construct of communicative competence. To recall, Hymes opposed the view that only knowledge of

formal structure was relevant to a theory of competence, arguing instead that competence consists of **variable** knowledge about patterns of language use. “Communicative competence involves knowing not only the linguistic code, but also what to say to whom, and how to say it appropriately in any given situation” (Saville-Troike, 2003: 18). Additional disciplinary sources of language socialization research are to be found primarily within scholarly domains privileging various integrated views of language and culture, including, as noted above, linguistic anthropology, but also sociocultural–historical psychology, discourse analysis, and, more recently, cultural and practice theory.

Second language socialization research draws its views on cognition as an integrity of language, mind, and society from sociocultural psychology as originally outlined by Vygotskij (1962, 1978) and Leontiev (1981), with its emphasis on the development of higher-order cognitive functions from the outside in, that is, through social interaction with adults or other experts where performance is assisted. Novices are seen to develop capacities through active and selective participation in social practices at various degrees of engagement (from legitimate peripheral to full participation) and, in so doing, to transform not only their own cognition, but also the qualities of the practices themselves (Lave and Wenger, 1991) (*see Communities of Practice*).

A perspective on language integrating linguistics and social practice is taken from discourse analysis, a field of linguistics that emphasizes the study of language in use, examining how the elements of language systems are used for communicative purposes within and across particular social and cultural contexts. “Language is seen as fully integrated into sociocultural behavior, as both the result and the creator of context and structure” (Watson-Gegeo and Nielsen, 2003: 163).

In recent years, language socialization research has been influenced by “...the poststructuralist realization that learning is a non-linear, relational human activity, co-constructed between humans and their environment, contingent upon their position in space and history, and a site of struggle for the control of power and cultural memory” (Kramsch, 2002: 5). Poststructuralist and critical theories attempt to unite research on language and power and thereby to enhance the relevance of this research through agendas of social critique. These approaches highlight the role of language as symbolic capital and the subtle mechanisms by which power is circulated and reproduced in the discourse of socialization practices. Whereas language socialization was once portrayed as inevitable, desirable, and uniformly accessible, many researchers are now sensitive to the dynamic

and negotiated nature of the process, including the possibility that novices may not have ready access to socialization, and the fact that they are endowed with agency (to accept, accommodate, resist, or reject socialization processes).

Foci and Methodologies

A constant in language socialization (LS) studies is their emphasis on developmental processes and their longitudinal design, requiring selection of research sites believed to be places of transformation, whether such change is observed in classrooms or chatrooms, in homes, schools, or workplaces. Research involving educational contexts has examined foreign and second language classrooms and participants of varying age, but has also examined the role of socialization practices in technology-enhanced learning environments, study-abroad programs, and adult language and literacy courses. The research on second language socialization is not limited to educational contexts, however, but also includes studies in homes, workplaces, and bilingual or multilingual communities.

Whereas the original methodology combining ethnography and microlinguistic analysis has remained at the core of the approach, language socialization research has also been enriched and refined in the intervening years through inclusion of a variety of definitional constructs, data elicitation practices, and analytic procedures. Thus, ethnographic approaches, in particular the ethnography of communication (EC), feature prominently in the literature on second language socialization. However, this literature is characterized by great variety in the choice of theoretical and analytic emphasis. Some studies take their primary inspiration from sociocultural psychology, examining the mediating role of language in the development of higher-order cognitive functions as individuals participate in ‘activity systems’. Other studies focus less on the achievement of a ‘thick description’ of the surrounding sociocultural context (Geertz, 1973) and more on detailed analysis of particular discourse practices, often in second language classrooms. Still others, often inspired by poststructuralist theories of second language learning, investigate autobiographical representations of language socialization as they are presented in narrative and other texts.

Language socialization research varies considerably with respect to focal scale. Some studies involve minimal engagement with large numbers of participants, whereas others scrutinize the activity of one participant in multiple ways. Some studies examine the activities of participants in a range of contexts, whereas others confine their perspective to one (the

classroom, the chatroom, the workplace). Time frames for longitudinal studies also vary considerably, with some studies emphasizing microgenesis of skills and capacities over relatively short developmental periods, such as one academic semester, and others attempting to trace ontological or developmental histories over periods of years or entire life spans.

Overview of Second Language Socialization Research

The overview of second language socialization research presented here is organized by primary methodological emphasis. Although division of studies into such categories is admittedly somewhat artificial, risking simplification, this descriptive account also provides a clear organizational framework for characterizing how differing epistemological goals and methodological resources are organized in illustrative individual studies. Therefore, the review begins with studies that are primarily ethnographic in orientation and then proceeds to examine the activity-theoretical approach, research examining socialization in second language classroom discourse, and investigations based on narrative study.

Ethnographic Approaches

As defined by Duff (2002), the EC is a “composite of approaches” (p. 292) for conducting qualitative or interpretive research on communication within or across cultures. EC combines etic and emic analyses of communication (i.e., outsider’s and insider’s views) as well as macro- and microanalyses of discourse in order to examine what a speaker needs to know in order to communicate effectively within a particular speech community and how he or she learns to do so (Saville-Troike, 2003). Ethnographic research normally requires prolonged engagement with the community under study and an effort at data triangulation, as well as careful observation of authentic communicative practices in their naturally occurring context.

Within ethnographic approaches, microlevel analyses of discourse are organized around the “communicative event” as the basic descriptive unit, defined by “a unified set of components throughout, beginning with the same general purpose of communication, the same general topic, and involving the same participants, generally using the same language variety, maintaining the same tone or key and the same rules for interaction, in the same setting” (Saville-Troike, 2003: 23). Within contemporary second language socialization research, routine cultural practices are often mined in attempts to uncover the cultural or ideological underpinnings of everyday

language and the processes by which accompanying values or worldviews are inculcated in children or other novices.

Thus, in many cases, data elicitation begins with a multimethod, holistic approach to thick description (Geertz, 1973) of socialization practices, followed by a choice of relevant communicative events based on this emic analysis. These events are then observed closely and repeatedly as they are audio- or video-recorded and transcribed. The choice of method for microanalysis of socialization practices varies greatly, with some researchers opting for close analysis of emergent routines through conversation analysis and others choosing various other forms of discourse or interaction analysis.

The work of Duff (1995, 2002) offers several examples of ethnographic research, examining the interface between macro- and microlevels of educational discourse in secondary schools. Duff (1995) investigated the consequences of post-Soviet educational reform in English language immersion classes in a progressive Hungarian school. Duff’s study revealed how macrolevel changes are reflected in the qualities of classroom discourse as students in English-medium history classes are socialized to accept the replacement of traditional oral assessment through recitation (*felelés*) by student-led activities and open-ended discussion. More recently, Duff (2002) performed an ethnographic study in a mainstream Canadian high school with a large proportion of students who speak English as a second language. Concerned with the creation of cohesive and harmonious school communities that nonetheless accommodate diversity, the study analyzed the sequential organization of talk in a social studies course, including the organization of turn taking, alignment, and other features of participation. Results revealed that the teacher’s emphasis on social justice and empathy for others was enacted in her attempts to allocate turns equitably and to have all students, local and nonlocal, draw cultural connections based on personal experience. However, some ESL students often declined to participate in discussions where they were positioned in various ways as outsiders. Thus, the teacher’s efforts to foster a cohesive classroom community in which all members participated were often unsuccessful.

Another exemplary ethnographic study was performed by Willett (1995), focusing on the participation of ESL children in the daily routines of a mainstream first-grade classroom in the United States. Willett investigated the qualities of interactional routines embedded in communicative events as four children acquire English in first-grade classroom. The study reveals how the “micropolitics of

social interaction” (p. 475) in this case positioned the three girls in the study as successful learners, able to collaboratively appropriate desirable social, linguistic, and academic competence. The one male participant, however, needed a public status in order to build solidarity with other boys. Having first acquired the public and often crude language used by these boys, he was isolated from his peers and was subsequently deemed an excessively needy and problematic student.

Additional ethnographic studies of note have been carried out in a wide array of contexts. Studies of schooling include Moore’s (1999) report of major discontinuities between community and classroom language socialization practices in a Cameroon village, a gap that contributes to widespread rejection of French-based schooling due to the inaccessibility of the French language. Miller’s (1999) ethnographic study of ESL students’ socialization in a mainstream Australian high school showed how Chinese students’ use of English is not legitimated in the same way that it is for European immigrants.

Ethnographic studies of socialization in multilingual workplaces include, for example, Goldstein’s (1997) study documenting the complex interaction of community resources and identities combining to limit access to English for Portuguese immigrant factory workers. An ethnographic case study by Li (2000) focused on the pragmatics of higher-stakes social communication, illustrating how one woman, a Chinese immigrant to the United States, came to internalize second language norms and develop communicative competence in English through participation and exposure to social interactions and assistance from experts and more competent peers.

A number of studies have examined the study-abroad sojourn as a context for language socialization. DuFon’s (2000) study of the acquisition of linguistic politeness by U.S. sojourners in Indonesia revealed conflicts between the participants’ own gender- and religion-related identities and the parallel options available in Indonesian. Talburt and Stuart (1999) discussed the manner in which an African American woman studying in Spain was subjected to continuous and humiliating emphasis on race and sexuality in her interactions with Spaniards. Kline (1998) reported that American women studying abroad in France sought refuge in literacy following repeated encounters with sexist and hostile attitudes in the French-speaking community.

Sociocultural Theory and Language Socialization

Researchers primarily inspired by sociocultural perspectives, including activity theory (Vygotsky, 1978; Leontiev, 1981), have also begun to contribute to

the literature on second language socialization. As Kasper has noted (2001), sociocultural theory and language socialization perspectives differ in their epistemological goal: whereas sociocultural theory aims to explain the mediating role of language (and other symbolic or physical tools) in the development of higher forms of cognition, language socialization strives toward an integrated account of language and culture acquisition. Nonetheless, the compatibility of the two perspectives derives from certain basic theoretical and methodological premises.

Just as LS strives to link individual processes to their sociocultural context, activity theory aims to overcome the traditional Cartesian dualism in the social science between the individual and surrounding social environment (Lantolf, 2000). It does so through the concept of mediation, or the observation that all human activity is mediated by culturally created physical and symbolic artifacts, including language.

Whereas LS studies aim to comprehend the norms of ‘speech communities’, activity theory defines the scope of sociocultural context in relation to the organization of practice. In any activity system, there exists a division of labor according to which certain roles are assigned or negotiated among the participants, and from which emerge the tacit or explicit rules that individuals and the community as a whole follow when interacting with one another and with mediating artifacts. The community of practice, an affiliated term, is seen to emerge from this division of labor and is the prime context in which individuals can work out common sense through (continuous) mutual engagement, a joint enterprise, and a shared repertoire of communicative resources (Wenger, 1998).

A crucial aspect of activity theory is its tracing of human behavior to historical rather than biological sources. The study of development is conceived as observation of genetic processes occurring over time. Language socialization research focuses primarily on two historical domains: ontogenesis (life history of individuals) and microgenesis (history of particular psychological functions over short periods of time). Thus, in practice, methodology of activity-theoretical research shares with LS a concern with prolonged, ecologically valid observation of human action.

From the perspective of activity theory, the meaning of human behavior arises from a need directed toward an object. The projection from the object to the outcome of the behavior is the motive. Motives are not always pre-established, but are dynamic and malleable and may be formulated in the process of activity itself.

An example of an activity-theoretical approach to language socialization is to be found in a study by

Lantolf and Genung (2002) documenting the history of one graduate student's failure to learn Mandarin Chinese as a participant in a summer intensive Chinese course. The participant, P.G., a colonel in the U.S. Army, is an experienced language learner and teacher specializing in applied linguistics who is required to complete a requirement of six credits in a non-Western language. The study focuses on the conflict between P.G.'s historically formed self-image as a good language learner and the rules for interaction imposed by the activity system of the classroom and institution, where an authoritarian methodology is enforced. The study traces the transformation over time in this learner's motives for participating in the course. Whereas initially, P.G. defined her goal as developing communicative competence in Chinese, when her efforts to do so were repeatedly thwarted, she reframed her efforts as related to success in the course so as to meet the requirement and fulfill her obligation to the Army in securing a graduate degree. Thus, the study documents the dynamism of learner motives and accompanying social and cognitive activity as they evolved through participation in the course.

Classroom Discourse

In research on the qualities of classroom discourse, the socialization perspective serves to illuminate the nature and function of interaction as a cultural medium for language learning, focusing on both socialization through language and socialization to use language. For example, in a study of beginning ESL classes in the United States, emphasizing socialization through language, Poole (1992) demonstrated that routine interactional sequences led by the teacher bear significant resemblance to American caregiver language behavior in general. In this context, the teacher/expert coconstructed learner responses, attributed collective task accomplishment to individuals, and avoided an overt display of hierarchical asymmetry, thus expressing cultural preferences for conjecture on the mental states of others, individual achievement, and suppression of power differentials. In a longitudinal study of similar aim, He (2003) examined the heritage Chinese-language school as a locus for socialization into cultural norms, focusing on the speech roles assigned to students. His study demonstrated the variability of novices' responses to socialization practices, showing how the opportunity to acquire Chinese and associated cultural values may be accepted or contested, even by young children.

For adults, socialization through a second language may present particularly complex problems related to language use and identity. Siegal (1996) presented a

case study focusing on the role of learner subjectivity in the acquisition of sociolinguistic competence by European women learning Japanese in Japan. The study examined the conflict concerning sociolinguistic appropriateness experienced by one learner in conversation with her professor, where unequal power and positionality exerted influence on the quality of the interaction. Although she did understand the pragmatics of appropriate demeanor for a woman in Japanese society, in attempting to craft a voice for herself as a professional woman in Japanese, the student manipulated honorifics, modality, and topic control in ways that sometimes resulted in inappropriate language use.

Other classroom discourse studies orient their analysis more closely toward socialization to use language. Ohta (1999) probed interactional sequences in a Japanese-as-a-foreign-language classroom, emphasizing how these sequences engage learners' participation. The study tracked the pragmatic development of a learner over the course of 1 year, demonstrating that active and peripheral participation in the routines of classroom language use shaped the learner's ability to use the follow-up turn of the Initiation–Response–Follow-up routine to perform assessments and other responses to interlocutors' utterances. Hall (1995) scrutinized the interactive environment of a first-year high school Spanish class intended to provide speaking opportunities. The teacher's primary method of developing and maintaining topical coherence took place through repetition and chaining of a small number of lexical items. This practice differs considerably from the ways in which topics are discursively established and managed outside the classroom and produces a limited repertoire of communicative practices for the students. Students in such classrooms are not socialized to use discursive forms and functions for engaging in complex, extended talk about a topic and, indeed, in the absence of overarching topic relevance, these students cannot orient to the talk in ways that permit coherent contributions.

With the arrival and widespread use of computer-mediated communications (CmC) technology in the language classroom, researchers have also begun to investigate the implications of CmC use for language socialization. For example, in a study focused on the development of pragmatic competence in the use of address forms (du vs. Sie), Belz and Kinginger (2003) examined the discourse of intercultural exchanges in German and English in the context of a telecollaborative language course. Internet-mediated contact with peers who are expert users of German offered participants in the United States many opportunities for assisted performance in socially acceptable use of the address form system in German.

Narrative Study and Second Language Socialization

The contemporary literature includes a number of narrative approaches to second language socialization, aiming to understand how multilinguals represent the process of language socialization and how this process impacts on the qualities of communicative repertoires. Research on the representation of language socialization examines learners' autobiographical accounts of language learning. Based on representations of language learning history, often written by exceptional learners and users of multiple languages, this research offers insights into the ontogenesis of multilingualism over time and in relation to personal identity and historical context.

Pavlenko (2001), for example, adopted a poststructuralist approach to narrative study in a series of studies linking L2 socialization to various aspects of identity. Poststructuralism is "understood broadly as an attempt to investigate and to theorize the role of language in construction and reproduction of social relations, and the role of social dynamics in the processes of additional language learning and use" (Pavlenko, 2002a: 282). Narrative study is a socio-culturally and sociohistorically situated literary analysis in terms of genre conventions, metaphors, and tropes (e.g., the self-made man, language learning as appropriation of voice) (Pavlenko, 2002b). Pavlenko (2001) posited cross-cultural differences in societal conceptions of normative gender-related identities. Based on a corpus of 30 second-language learning stories, Pavlenko analyzed learners' encounters with ideologies of gender and their associated discursive practices. She explored the dilemma of border crossers who find themselves in situations where their previous subjectivities cannot be legitimately produced and understood and who must choose to resist or produce new social identities, beginning with perception and critical examination of these identity options, through the processes of choosing assimilation or resistance and of undergoing gender socialization.

Narrative approaches may also be applied to the study of bilingual communicative repertoires, as exemplified in the work of Koven (1998) examining the performance of identity in narrative by Portuguese–French bilinguals. The study involved elicitation of the same oral narratives of personal experience in Portuguese and French, with analysis of communicative style and use of register in each. Development of communicative repertoires in each of the two languages was closely tied to the sociocultural context of socialization, such that, in effect, the participants appeared to be performing different

"selves" in each of their two languages. Having grown up in Paris, with family ties and frequent visits to rural Portugal, when narrating in French the participants employed contemporary urban speech styles expressing progressive values and gender roles in which, for example, women's self-expression is relatively unconstrained. When narrating in Portuguese, however, the same participants employed speech styles characteristic of rural settings and presented a more conservative version of their identity.

Taken together, these narrative approaches represent a promising new direction in the study of language socialization as a complex, lifelong process with consequences for discursive performance of identity.

Conclusion

Within second language studies, language socialization is now represented in numerous domains, including bilingualism, multilingualism, and foreign language learning in homes, workplaces, and educational settings of various kinds. Edited volumes (Kramsch, 2002; Bayley and Schecter, 2003) and a summary article (Watson-Gegeo and Nielsen, 2003) have marked the general acceptance of language socialization perspectives. At the same time, this growth has not gone uncontested, largely because the disciplinary roots and epistemology of socialization research are seen as fundamentally incompatible with those of the field known as Second Language Acquisition (SLA). Kramsch (2002), for example, expressed this conflict in terms of basic conceptual metaphors, with SLA preferring the Learner as Computer, and language socialization, the Learner as Apprentice. Historically, she noted, there has been little communication between these fields despite the fact that in practice (e.g., the practice of language learning and teaching) the goals of each may be seen as complementary, as, for example, when the aim of second language instruction is expressed as communicative development that requires precise knowledge of grammar and lexis. It is to be hoped that the complementarity of these approaches will increase in salience as researchers continue to design investigations of language learning.

Society and Language: Overview

Language

'Linguistics' may be somewhat blandly defined as the study of language. Such a characterization leaves out the all-important formulation of how such study is to be conducted, and where exactly the boundaries of the term 'language' itself lie. Broadly speaking, different branches of linguistics are concerned with language structure, acquisition, and use. 'Sociolinguistics' is one of the branches that is concerned more with the use of language than the other two aspects. And unlike branches like pragmatics and discourse analysis, which are also concerned with 'use,' sociolinguistics lays particular emphasis upon the social embeddedness of language. When we use the term 'language' as a general phenomenon, we refer to a system of arbitrary symbols used for human communication. Having 'human communication' as part of the definition of language makes it impossible to study language comprehensively without due regard to the social context of speech. Such an emphasis was not always explicit in linguistics.

Antecedents of Sociolinguistics

While sociolinguistics as a specially demarcated area of language study dates only to the early 1960s (e.g., Paulston and Tucker, 1997; Shuy, 1997: 23, who cite the summer of 1964 as a crucial time), attention to the social was implicit in many earlier studies. It is possible that just as most linguists accept that scholarly linguistics was first practiced in ancient India, culminating in Panini's *Astadhyayi* (ca. 500 B.C.E.), Panini may prove a pioneer of sociolinguistics too. The suggestion has been made that Panini's rules are, *inter alia*, "sophisticated attempts at capturing the stylistic preferences among variants which are characteristic of any living language" (Kiparsky, 1979: 1). In terms of a continuous lineage for modern

sociolinguistics, however, four western traditions have been most influential: historical and comparative linguistics, anthropology, rural dialectology, and the study of mixed languages.

Historical and comparative linguists became interested in modern speech forms (or 'dialects') for the possible light they could shed on theories of language change that had previously been based on written materials. Two branches of what is now called 'sociolinguistics' had strong 19th-century antecedents: the study of rural dialects in Europe and contact between languages that resulted in new 'mixed languages.' The work of Hugo Schuchardt (1882), Dirk Hesseling (1897) and Addison Van Name (1869–1870) challenged many of the assumptions of their contemporaries.

Even Saussure, who is most frequently associated with modern structuralism, stressed in his work that language was a 'social fact,' i.e., it belonged to a realm larger than that of the individual. A society is not just the lowest common denominator of its individuals. For Saussure, the concrete data of language (what he called '*parole*') are produced by individual speakers, but "language is not complete in any speaker; it exists perfectly only within a collectivity" (1959: 14).

In the early 20th century, structuralists in the United States were partly motivated by the need to describe rapidly eroding American Indian languages before they became extinct. Becoming acquainted with the cultural patterns of societies that were novel to them led scholars like Franz Boas, Leonard Bloomfield, and Edward Sapir to establish what became the foundations of studies of language, culture, and cognition. Such an anthropological perspective on language was a forerunner to some branches of sociolinguistics, especially the ethnographical approach.

The term 'sociolinguistics' appears to have been first used in 1952 by Haver Currie, a poet and philosopher who noted the general absence of any consideration of the social in the linguistic research of his day. Significant works on sociolinguistics appearing after this date include Weinreich's influential *Languages in contact* (a structural and social account

of bilingualism; 1953), Einar Haugen's two-volume study of the social history of the Norwegian language in America (1953), and Joos (1962) on the dimensions of style.

Emphases in Sociolinguistics

Chomsky's emphasis in the 1960s on an approach that abstracted language away from everyday contexts ironically led to the distillation of a core area of sociolinguistics, which was opposed to his conception of language. In a now infamous passage, Chomsky (1965: 3) argued that linguistic theory should be concerned primarily with an ideal speaker-listener in a completely homogeneous speech community, who knows its language perfectly and who is unaffected when applying his knowledge of the language in actual performance. While such an approach brought significant gains to the theory of syntax and phonology, many scholars felt that abstracting away from society could not lead to an encompassing theory of human language. This period marked a break between sociolinguists, who had an interest in language as communication within human societies, and the 'generativists,' who were interested in an idealized, nonsocial, psycholinguistic competence. Whereas the Chomskyan framework focused on what could be generated in language and by what means, the social approach tried to account for what can be said in a language, by whom, to whom, in whose presence, when and where, in what manner and under what social circumstances (Fishman, 1971; Hymes, 1971; Saville-Troike, 1982: 8). For the latter group, the process of acquiring a language is not just a cognitive process involving the activation of a predisposition in the human brain: it is a social process as well, that only unfolds in social interaction. The child's role in acquiring its first language is not a socially passive one, but one which is sensitive to certain 'environmental' conditions, including the social identity of the different people the child interacts with.

Dell Hymes (1971) was the principal objector to the dominance of Chomsky's characterization of what constituted the study of linguistic competence. He suggested that a child who might produce any sentence whatever without due regard to the social and linguistic context would be "a social monster" (1974: 75) who was "likely to be institutionalized." Hymes coined the term 'communicative competence' to denote our ability to use language appropriately in different settings. His stress on language use was in strong contrast to Chomsky's focus on the abstract code. Hymes' interest was not just in the production of sentences, but in characterizing the more social-bound aspects, such as the amount and volume of

talk in different communities, acceptability of silence, rules for turn-taking, amount of simultaneous talk, etc. In this view, there are rules of use without which the rules of grammar are, at best, abstractions (at worst, Hymes said, "useless"). William Labov (1972: xiii), whose name features prominently in the discipline, expressed uneasiness about the term 'sociolinguistics,' since in his view there can be no linguistics that is not social. Still others are slightly suspicious of the term, since it privileges the linguistic over the social. One distinction that is sometimes made is that between 'sociolinguistics' (proper) and the 'sociology of language.' Some scholars believe that the former is part of the terrain mapped out in linguistics, focusing on language in society for the light that social contexts throw upon language. For these scholars, the latter ('sociology of language') is primarily a subpart of sociology, which examines language use for its ultimate illumination of the nature of societies. One writer (Fasold, 1984, 1990) has attempted to capture this formulation by writing two scholarly books: *The sociolinguistics of society* and *The sociolinguistics of language*. While there is some basis for such a partition, and something to be gained by it, in practice the boundaries between the two areas of study are so flexible as to merit one cover term (although, as in this entry, there is a slight difference in nuance between 'sociology of language' and the more common and general term 'sociolinguistics'). Sometimes the distinction between the two orientations is expressed by the terms 'macrosociolinguistics' and 'microsociolinguistics.' As in other subjects, notably economics, macrostudies involve an examination of interactions at a broader level (the focus is broad, as in the study of multilingualism or language attitudes in a community). Microstudies examine finer patterns on a local level (e.g., the details of conversational structure or accents in a particular community). Macrosociolinguistics tends to overlap with applied linguistics to some extent, especially regarding language policy, language use in the domain of education, and the interface between dialect and standard. The two fields are separated by the greater interest among applied linguists in the psychology of language learning, especially in second-language acquisition. There is also a more practical orientation among applied linguists in their educationally focused work on curriculum issues, materials development, language assessment, remediation, and so forth.

'A Language' as a Social Construct

Up to now we have been dealing with 'language' in the abstract, as a collective term. When we turn to 'languages' as individual entities, the possession of specific societies, we run into problems of definition.

It may come as a surprise to the nonspecialist to learn that linguists are unable to offer a definition of what constitutes 'a language' (as against overlapping entities such as 'dialects'). For this reason the term 'variety' is employed as a neutral one, referring to any form of speech. The term 'variety' is particularly useful when the status of a speech form is unclear and one wishes to avoid prejudging the issue whether a given speech form is (in popular terms) a 'language' or a 'dialect.' In many instances the boundaries between languages are far from clear, especially where historical and geographical links are involved. Mutual intelligibility might seem a useful test of whether two varieties are distinct or not. In practice, however, it is almost always sociopolitical criteria that decide the status of a variety, rather than linguistic ones.

The case of Norwegian and Danish provides a clear illustration of the sociopolitical nature of the distinction between what counts as a language and what does not. For four centuries Norway was ruled by Denmark. Danish was considered the official language, with Norwegian speech having dialect status (i.e., it was considered a dialect of Danish). Upon Norway gaining its political independence in 1814, Norwegian was declared an 'official language,' distinct from Danish. The same has happened in what was formerly Yugoslavia, where Serbian and Croatian did not have independent status but were considered as 'eastern' and 'western' variants of the same language called Croato-Serbian (or Serbo-Croatian). With the bloody conflict that accompanied the break-up of the federation in the 1990s, differences between the two varieties were emphasized, and each of them have come to be considered independent 'languages.'

The opposite case is that of two varieties classified by linguists as distinct languages but considered the same by a community. Linguists consider creole forms of language to be separate systems from the languages they drew much of their vocabulary from (e.g., Jamaican Creole English is a different system from the standard English of southern England). Yet their coexistence of the two systems in the same society and the dominance of the more standard forms of English may not always lead to the recognition of the two as separate languages.

Language Is Not a 'Given'

The work of Le Page (1978) and Le Page and Tabouret-Keller (1985) has been influential in showing the potential diffuseness of the notion of 'a given language' and the way that the identities of groups of people are shaped by, and in turn shape, language use. For Le Page and Tabouret-Keller (1985: 14), linguistic behavior is "a series of acts of identity in which

people reveal both their personal identity and their search for social roles." In this view, identity and language use are potentially fluid; and individuals have priority. Well-defined social groups may or may not exist beforehand. In the highly multilingual and heterogeneous communities they studied in the Caribbean, the researchers found it necessary to pay attention to the processes of emergence and disintegration of identities in relation to linguistic processes of focusing and diffusion. The terms 'focusing' and 'diffusion' are based on the imagery of the movie screen. Speech acts are acts of projection: the speaker projects his inner universe via a common language (with its nuances of grammar, vocabulary, and accent) or via a particular choice of language where choices exist (in multilingual settings). The speaker implicitly invites others to share his projection of the world, insofar as they recognize his language as an accurate symbolization of the world, and to share his attitudes toward it (Le Page and Tabouret-Keller, 1985: 181). The feedback he receives from those with whom he talks may reinforce his perceptions, or they may cause him to modify his projections, both in their form and content. To the extent that he is reinforced, his behavior in that context may become more regular, more focused; to the extent that he modifies his behavior to accommodate others, it may for a time become more variable, more diffuse. In time, however, the behavior of the group – that is, he and those with whom he is trying to identify – will become focused. The individual thus creates for himself patterns of linguistic behavior so as to resemble those of the group or groups which he wishes to be identified at different times. Le Page stressed four provisos to this hypothesis:

- a. that one can identify the groups
- b. that one has adequate access to the groups and the ability to analyze their behavioral patterns
- c. that the motivation for joining the group must be sufficiently powerful and is either reinforced or lessened by feedback from the group
- d. that one has the ability to modify one's behavior.

Le Page and Tabouret-Keller's model thus teases out the kind of variation evident in a society from its historical moments: is it a society in the making or in flux (diffuse) or is it, historically speaking, focused?

Sociolinguistics Is Not Prescriptive

Following studies like those of Le Page and Tabouret-Keller, sociolinguists now accept the idea that language is partly inherited and partly made and remade by its speakers. This perspective does not fit well with the traditional views one encounters among some writers, educationists, parents, and policy makers.

The latter are more concerned with inculcating and transmitting a formal, written, and relatively homogeneous standard form of a language. There is nothing wrong with this ideal, provided that all citizens have access to the resources that are necessary for the mastery of the standard. Sociolinguists and linguists generally do, however, insist that inculcation of a standard norm among schoolchildren should not be accompanied by the denigration of the vernacular forms of language that pupils bring to the school. Children have in place a full language system, capable of considerable communicative nuance, before arriving at school. The vernacular has been demonstrated (see Labov, 1969) to be rule governed, even if it does not always meet the preconceived notions of correctness that two centuries of prescriptivism have inculcated among educators. Linguists (see Palmer, 1971; Crystal, 1971) have long shown the subjectivity and contradictions of the prescriptive rules insisted on by teachers ('don't split infinitives'; 'two negatives make a positive'). For English, these norms evolved over a period of time after considerable subjective pronouncements by 18th-century writers and grammarians (see Milroy and Milroy, 1985). They can easily be shown to have logical flaws. (In Latin, the infinitive occurs as a single word, which cannot be split; English, by contrast, expresses the infinitive in two words – *to* + verb – which occasionally permits an intervening adverbial element, as in *I want you to really try, for my sake*. The insistence that two negatives make a positive in English is nullified by prescriptivists' views of collocations of three negatives, as in *Nobody never said no such thing*. Prescriptivists would not accept this sentence as grammatical, even though the mathematics they appeal to makes it negative, rather than positive.) Prescriptive judgments ultimately serve upper- and middle-class interests, stamping their ideology as relating to 'taste,' 'discrimination,' and 'culture.' The sociologist Basil Bernstein (1974) argued that the orientation of children from working-class backgrounds toward language was 'restricted' compared to the relatively 'elaborated' norms of the middle classes. And since school success demanded the mastery of the latter, children from working-class backgrounds were less likely to succeed, given their limited access to those norms. Furthermore, their class position militated against acquiring norms that are associated with forms of authority and/or lifestyles that they see no point in emulating. Bernstein's dichotomy between restricted and elaborated codes has been argued to be more an assumption than a linguistic reality (Labov, 1969; Edwards, 1979). However, his foregrounding of language and class issues in education is a lasting contribution to the sociology of language.

Society

A coherent theory of language in society can unfold only within a particular theory of society. Within sociology there are three dominant theories of human society, and there is little agreement between their adherents. The three theories (or sets of ideas about how society works) that have informed different approaches to sociolinguistics are 'functionalism,' 'Marxism,' and 'interactionism.'

Functionalism

Functionalism was the dominant theoretical perspective in western thought between the 1940s and mid-1960s. It pursued the view that a society may be understood as a system made up of functioning parts. To understand any part of society (e.g., the family or school), the part must be examined in relation to the society as a whole. Haralambos and Holborn (1991: 8) stressed the analogy with biology: just as a biologist might examine a part of the human body (e.g., the heart) in terms of its contribution to the maintenance of the human organism, the functionalist examines a part of society (e.g., the family) in terms of its contribution to the maintenance of the social system. The social system has certain basic needs (or functional prerequisites) that must be met if it is to survive (e.g., food and shelter). The value of the function of any part of society lies in its contribution to the maintenance of the overall whole. There is a certain degree of integration between the parts (social institutions) that make up the society. Functionalists argue that the order and stability they see as essential for the maintenance of the social system are provided by 'value consensus,' i.e., agreement about values by members of society. In this view, two major occupations of the sociologist are the study of social subsystems and the value consensus that binds them together. Concepts stressed within (but not exclusive to) this brand of sociology that are particularly useful to sociolinguists include the following.

Culture Although the popular sense of this word stresses 'high' culture (e.g., musical, literary, and artistic achievements), in the technical sociological-anthropological sense, the culture of a society is "the way of life of its members; the collection of ideas and habits which they learn, share and transmit from generation to generation" (Linton, 1945). Culture in this sense is a "design for living" that defines appropriate or acceptable ways and forms of behavior within particular societies.

Socialization ‘Socialization’ refers to the process through which people learn the culture of their society. Primary socialization takes place in childhood, usually within the family. From a linguistic point of view, the peer group (e.g., the child’s circle of playmates within and outside the home) soon overtakes the parents as the main reference group in transmitting linguistic behavior. Socialization continues into adulthood, and upon permanently entering a new society that differs considerably from one’s own a person may undergo resocialization.

Norms and Values “A norm is a specific guide to action which defines acceptable and appropriate behavior in particular situations” (Haralambos and Holborn, 1991: 5), as evident in dress codes at school, at home, and at a party. In the course of socialization, ‘norms’ are inculcated by rewards (a sweet, a kind word) or punishments. Some norms become enacted in law to serve a larger society, e.g., a law forbidding nude bathing or the exposure of a woman’s face in public in some societies. ‘Values,’ on the other hand, provide general guidelines regarding qualities that are deemed to be good, desirable, and of lasting worth. In many modern societies, the value placed on human life is a basic one that determines norms of behavior (e.g., standards of hygiene, settling of disputes, work safety regulations, etc.). Functionalist sociology proceeds from the premise that unless norms are shared, members of society would be unlikely to cooperate and work together. In this view, an ordered and stable society requires shared norms and common values.

Status and Role ‘Status’ refers to social positions that society assigns to its members (not just the high ones, as in popular parlance). Such a status may be ascribed, i.e., relatively fixed by birth (e.g., one’s gender status, or aristocratic titles in some societies); or it may be achieved. The latter refers to statuses that result from some degree of personal endeavor, e.g., a career as a teacher or an athlete. In a caste-based society, one’s occupation is ascribed, i.e., determined by birth; whereas in other societies it is achieved (i.e., by choosing one’s training). According to Haralambos and Holborn (1991: 7) each status in society is accompanied by a number of norms that define how an individual occupying a particular status is expected to act. This group of norms is known as a ‘role.’ Social roles regulate and organize behavior. In the course of a day, a person may play out several roles: that of teacher (at work), mother and wife (at home), client (with a bank), poet (at a leisure society), etc. These roles are defined by their interactive nature: the role of doctor usually assumes the existence (if not the presence of) a patient, that of mother the existence

of the child, and so on. Each of these roles calls upon different forms of behavior, including linguistic behavior.

Marxism

Since the 1970s Marxist approaches in sociology have become increasingly influential. Differing sharply from the functionalist belief that all social groups benefit if their society functions smoothly, Marxism stresses fundamental differences of interest between social groups. These differences ensure that conflict is a common and persistent feature of society, not just a temporary disturbance of the social order (as functionalists believe). Karl Marx (1818–1883) stressed the economic basis of human organization, which could be divided into two levels: a base (or infrastructure) and a superstructure. The ‘base’ is determined by the forces of production (e.g., the raw materials and technology of a particular society) and the social relationships of production (e.g., social relationships that people enter into – such as manager and worker – to produce goods). The other aspect of society, the ‘superstructure,’ is made of the political, legal, and educational institutions, which are not independent of the base but shaped by it. Marx believed that all societies in historical times contain basic contradictions that preclude them from existing permanently. These contradictions, involving the increasing exploitation of one group by another (e.g., the exploitation of serfs by lords in feudal times), have to be resolved, since a social system containing such contradictions cannot survive unchanged.

The concepts that Marxists emphasize in their studies include social class; exploitation and oppression; contradiction, conflict, and change; and ideology and false consciousness. ‘Class’ denotes a social group whose members share a similar relationship to the means of production. Essentially, in capitalist societies, there is the ruling class, which owns the means of production (e.g., land, raw materials) and the working class, which must sell its labor power to earn a living. In feudal society the two main classes are distinguished relative to ownership of the land: the feudal nobility who owns it and the landless serfs who work it.

‘Exploitation’ in this theory is a technical term that stresses that the wealth produced by the labor power of workers is appropriated in the forms of profits by the ruling class. ‘Ideology’ within Marxist theory refers to the set of dominant ideas of an age: it emanates from the control of the ruling classes of the institutions of the superstructure. Such ideas serve ultimately to justify the power and privilege of the ruling class “and conceal from all members of society the basis of exploitation and oppression on which

their dominance rests” (Haralambos and Holborn, 1991: 14). A clear example comes again from the feudal age in Europe, when the dominant concepts were honor and loyalty, which appeared to be the natural order and were celebrated in literature and implicit in superstructural institutions such as the law courts and education. Similarly, according to many theorists, in the capitalist age, exploitation is disguised by the ideology of equality and freedom, which appear to be not just sensible and true but natural and desirable. This, Marxists argue, conceals the reality that capitalism involves fundamentally unequal relationships: workers are not ultimately ‘free’ since they are forced to work to survive: all they can do is exchange one form of wage subordination for another.

Interactionism

A third school of thought within sociology, less influential than the previous two, proceeds from a bottom-up approach of examining small-scale encounters, rather than large-scale social systems. It seeks to understand action between individuals. Haralambos and Holborn (1991: 15) emphasized that interactionism begins from the assumption that action is meaningful to those involved, and that those meanings are accordingly not fixed, but created, developed, modified, and changed within the actual process of interaction. Not only is the meaning of a social encounter a negotiated entity, but the individual develops a ‘self-concept’ (or idea of oneself) according to the interaction processes he or she takes part in and according to the way he or she is evaluated therein. For the interactionist, social roles are not as clearly defined as within functional theory. Furthermore, interactionists argue that roles are often unclear, ambiguous, or vague. This may provide actors with considerable room for negotiation, improvisation, and creative action.

Much sociolinguistics has proceeded implicitly from a functionalist perspective of society, although it must be said that within the discipline the linguistic tends to overshadow the sociological. The latter is often considered useful, largely for informal background information and orientation. Marxist approaches are not typically emphasized in the West, and while the skepticism with which Marxist/communist political practice has come to be viewed worldwide is understandable, from a scholarly point of view, many of the insights emanating from sociolinguistics do fit the Marxist critique of social systems quite well. Some sociolinguists have explored the linguistic ramifications of rule, control, and power. And class differences (which often criss-cross with gender or ethnicity) remain at the heart of studies of

sociolinguistic variation. Interactionism, which may not seem as substantial a sociological approach as the other two, has nevertheless inspired some important work in sociolinguistics (*see Interactional Sociolinguistics*).

Language in Society, Society in Language

A concern for the ‘human communication’ aspect within the definition of language implies attention to the way language is played out in societies in its full range of functions. This function is not just ‘denotational’; the latter term refers to the process of conveying meaning, referring to ideas, events, or entities that somehow exist outside language. Even while primarily concerned with this function, a speaker will inevitably give off signals concerning his or her social and personal background. Language is accordingly said to be ‘indexical’ of one’s social class, status, region of origin, gender, age group, etc. The term ‘index’ here is drawn from semiotic theory (or the science of signs), in which it refers to a particular relation between a sign and the object it stands for. In the sociolinguistic sense ‘index’ refers to certain features of speech (including accent) that indicate an individual’s social group (or background); the use of these features is not exactly arbitrary, since it signals (or indexes) that the individual has access to the life-styles that support that type of speech.

The relationship between region of origin, age, and – especially – social status and characteristic ways of using language are emphasized in ‘variation theory,’ as developed by William Labov (1966). Variationists use correlational techniques in revealing the relationship between linguistic variables (e.g., a vowel sound that has different variants that result in different accents) and social variables (age, gender, class, etc.). This is a vibrant and rigorous branch of sociolinguistics – to the extent that many characterize it as ‘core sociolinguistics’ or ‘sociolinguistics proper.’ Many sociolinguistics, however, argue that correlation does not capture the complex way in which language is intertwined with human existence. That is, they stress that talk is not just a reflection of social organization; rather, it is a practice that is one of social organization’s central parts. This approach has informed much work on language and gender in linguistics. In earlier gender and language research (*see Lakoff, 1975*) the main aim was to demonstrate a broad linguistic split between the sexes. Subsequent researchers went beyond the descriptive framework to an action-research mode that popularized the argument that languages could be sexist – that is, they could discriminate against women by presenting things from a male perspective (*see, e.g., Spender,*

1990). Language thus not only reflects existing inequalities but also helps to sustain and reproduce them, unless challenged. Subsequent gender research has increasingly become more nuanced. Eckert (1989) stressed the interplay between gender and social class in setting up various overlapping identities. From anthropology and gay studies has come the notion that a simple two-way dichotomy is misleading; there are differing degrees of masculinity and femininity (Johnson and Meinhof, 1997; Kulick, 2000).

Similar arguments hold for sociolinguistic approaches to ethnicity. In some societies, ethnicity may be more salient than class stratification, and language may play a key role in reflecting and indeed in maintaining and 'reproducing' an ethnic identity. Ethnicity is notoriously difficult to define and may not be as objective a phenomenon as sometimes assumed. Edwards (1985: 8) quoted Weber (1968), who regarded ethnic groups as "those human groups that entertain a subjective belief in their common descent ... it does not matter whether or not an objective blood relationship exists. Ethnic membership ... differs from the kinship group precisely by being a **presumed** identity." Sociolinguists therefore argue against the notion of a 'primordial ethnicity' that one sometimes finds in the literature on language maintenance. After all, group identity can survive language shift and frequently does. On the other hand, it is difficult to imagine a sense of ethnicity that does not entail significant differences in language use (e.g., religious and cultural vocabulary and nuances of accent are well attested in ethnic dialects). Postmodern urban people of the 21st century frequently have multiple identities, playing out a number of roles in a single day, each of which may require different language choices.

The idea was once popular in linguistics and anthropology that language and thought are more closely entwined than is commonly believed. An extreme form of this belief is what has come to be known as the 'Sapir-Whorf hypothesis': It is not just that language reflects thought; but conversely, thought is influenced by the language one is 'born into.' Mind, according to this hypothesis, is in the grip of language, and so are social consciousness and organization. Edward Sapir, and – especially – Benjamin Lee Whorf were led by their studies of Amerindian languages to argue that speakers of certain languages may be led to different types of observations and different evaluations of externally similar phenomena. According to Whorf (1956: 213), "we dissect nature along lines laid down by our native language." He said that using a language forced us into habitual grooves of thinking, almost like putting on a special pair of glasses that heighten some aspects of the

physical and mental world while dimming others. One example provided by Whorf concerned the distinction between nouns and verbs in Hopi as opposed to English. The Hopi terms for 'lightning,' 'wave,' 'flame,' 'meteor,' 'puff of smoke,' and 'pulsation' are all verbs, since events of necessarily brief duration fall into this category. The terms for 'cloud' and 'storm,' on the other hand, are of just enough duration to qualify as nouns. Another of Whorf's striking examples concerns tense and time. Whereas English dissects events according to their time of occurrence (relative to the act of speaking), Hopi expresses other categories in the verb, notably the kind of validity that the speaker intends the statement to have: is it a report of an event, an expectation of an event, or a generalization or law about events?

The Sapir-Whorf hypothesis is a thought-provoking one, whose strong form suggests, among other things, that real translation between widely different languages is not possible. The hypothesis has proved impossible to test: how would one go about ascertaining that the perceptions of a Hopi speaker concerning the world are radically different from that of, say, a French speaker? Generative linguists today insist that there are limits (or parameters) along which languages vary. In appealing to the notion of deep structure (or its more recent mutations), this school of linguistics stresses an underlying capacity for language that is common to humans. What seem to be radical differences in the grammatical structure of languages are held to operate 'on the surface,' as mappings from an abstract and quasi-universal deep structure. Linguists feel safer in accepting a 'weak form' of the Sapir-Whorf hypothesis: that our language influences (rather than completely determines) our way of perceiving things. But language does not grip us so strongly as to prevent at least some individuals from seeing things from different perspectives, from forming new thoughts and ideas. Within sociolinguistics, studies in the way that languages influence each other (by borrowing and mixing) also cast doubt on the strong form of the hypothesis. As Gillian Sankoff (1986: xxi) put it: "my conviction [is] that in the long term language is more dependent on the social world than the other way around ... Language does facilitate social intercourse, but if the social situation is sufficiently compelling, language will bend."

Types of Societies, Types of Language?

Societies may be characterized in terms of their complexity, as defined by their size, hierarchical organization, specialization of tasks, and interaction with other societies. It is important to note that

there is no linguistic analogy to this. Languages cannot be arranged in a list from least complex to most complex. The structure of a language does not correlate with the complexity of the communities that typically use them. In terms of morphology, syntax, and semantics, a language of an isolated mountain-bound community in the Himalayas is no less complex than any of the six world languages of the United Nations. The poet-cum-linguist Sapir (1921: 219) put it as follows: "When it comes to linguistic form, Plato walks with the Macedonian swineherd, Confucius with the head-hunting savage of Assam." Sapir's student, Whorf (1956: 84), who was intimately acquainted with the structure of Hopi and other Amerindian languages, was just as emphatic, if less poetic:

The relatively few languages of the cultures which have attained to modern civilization promise to overspread the globe and cause the extinction of the hundreds of diverse exotic linguistic species, but it is idle to pretend that they represent any superiority of type. On the contrary, it takes but little real scientific study of preliterate languages, especially those of America, to show how much more precise and finely elaborated is the system of relationships in many such tongues than is ours.

A reverse argument sometimes holds: people maintain that languages rich in inflections or in ways of combining basic grammatical units (morphemes) into words are perhaps too complex to function as languages of wider communication. Conversely, they suggest that the inflectional simplicity of English enables it to be effective as a language of international transactions. Several things are wrong with this argument. In the first place, notions of complexity should not be limited to the morphology of a language. Modern linguistics emphasizes the enormously complex organization of all languages. One language might appear to be morphologically richer on the surface, but a relatively simpler morphology (as with English) has to be made up in other components of the grammar – in the syntax and lexicon. If we are to look for reasons for the spread of one language over another, the wrong place to start would be the structure of the language, as Edwards (1995: 40) forcefully suggested:

It is [...] clear, to the modern linguist at any rate, that these varieties [dominant languages] achieved widespread power and status because of the heightened fortunes of their users, and not because of any intrinsic linguistic qualities of the languages themselves. The most common elements here have to do with military, political and economic might, although there are also examples in which a more purely cultural status

supports the lingua franca function. However, in this latter case, the cultural clout which lingers has generally grown from earlier associations with those more blatant features just mentioned. The muscle, in any case, which these languages have, derives from the fact that their original users control important commodities – wealth, dominance, learning – which others see as necessary for their own aspirations. The aphorism 'all roads lead to Rome' has linguistic meaning too.

It is sometimes said that if languages are all linguistically equal, they are not all sociolinguistically equal. In this vein, Joseph (1987: 25–39) pointed to the effects of print literacy and standardization in giving some forms of language and some languages an advantage over others, so that certain forms of language come to be seen as more important than others. But this should not be taken to mean that some languages are better placed in an absolute sense to serve a range of sociolinguistic functions (e.g., in formal speeches, writing, or television) than others. Every language has the potential to add to its characteristic vocabulary and ways of speaking if new roles become necessary. Some languages have a superior technical vocabulary to that of others in certain spheres. This is a difference in actuality rather than in potential.

Multilingualism: One Society, Many Languages

Many countries, especially in the West, attach special significance to one of their languages over others, adhering to an ethos of 'one state, one language.' Many of the states of Europe arose during a period of intense nationalism, with accompanying attempts to make national borders coterminous with language (and vice versa). The dominance of European powers in modern history has made this seem a desirable situation, if not an ideal one. The nonaligned sociolinguist instead points to the essentially multilingual nature of most human societies and to the fact that there are almost no countries in the world – even in western Europe – where everyone speaks, or identifies with, one language. In statistical terms, Grosjean (1982: vii) estimates that about half the world's population is bilingual. Romaine (1989: 8) points out further that there are about 30 times as many languages as there are countries. Even countries like France and England, which we are tempted to think of as monolingual, have, in fact, a vast array of languages within their borders. In France, for example, the following languages are still in use: French, Breton, Flemish (Vlaams), Occitan (Languedocien), Catalan (Catalan-Valencian-Balear), Basque (Navarro-Labourdin and Souletin varieties), Alsatian (a dialect of Allemanisch), and Corsican.

While multilingualism is not uncommon throughout the world, many schools have a policy that recognizes (and replicates) the hierarchy of relations within a territory and in the world as a whole. Only a small proportion of the 5000 or so languages of the world are used at the secondary level as media of instruction, and still fewer are used at the university level. Schools have often downplayed the value of the ‘vernaculars’ by minimizing their use in classrooms or recognizing them only as means of facilitating competence in the dominant language(s). Since the 1950s, and more especially since the 1970s, educationists have begun to recognize that multiculturalism is not a transient phenomenon. Sociolinguists are generally sympathetic to an approach that gives recognition to – and valorizes – as many of a society’s languages as possible. This is in keeping with a holistic approach that is sensitive to the needs of children from different backgrounds (‘bottom up’) and not just the bureaucratic needs of the state (‘top down’).

Language Variation and Contact between Languages

These two branches of sociolinguistics (‘language variation’ and ‘language contact’) show above all others how much language and society influence each other. Some variation studies that are concerned with ‘style, situation, and function’ deal with the importance of contextual factors in determining different registers, styles, and genres. They also deal with the use of language in specific domains and functions, such as in advertising, religion, business, and e-mailing. The notion of a ‘domain’ is a particularly useful one. Fishman (1965) defined a domain as a sphere of activity arising from combination of specific times, settings, and role relationships, which results in a specific choice of language or style. The notion of ‘register’ is a linguistic counterpart of the sociological concept of domain. A register (Halliday *et al.*, 1964) refers to variation according to the context in which language is used. Relatively well-defined registers include the language of the law, the language of science, and the language of hip hop or jazz. Whereas register studies focus upon language use relatively independent of the users, social dialectology does the reverse. Dialects and social groups in the modern Labovian tradition are central to an understanding of language variation and change. The emphasis in this tradition falls upon the finely nuanced differences within a language according to social groupings, based especially on class, gender, ethnicity, and region. The subfield of language contact stresses the reality that societies are rarely monolingual; languages exist amidst other languages. The idea of a pure and self-contained language is a poor, simplifying assumption,

compared to the challenges of studying the ways in which speakers of different languages influence each other – how new languages (e.g., pidgins, creoles, ‘New Englishes’) may be borne out of struggle and how multilingualism is ‘managed’ by speakers at a microlevel and by societies at a macrolevel.

Social Interactions via Language

This section serves to introduce many of the ‘Language in Society’ entries covered in this encyclopedia (specifically excluding variation theory and language contact, which are covered elsewhere). The concept of communicative competence, as cited above, describes and accounts for the knowledge that people have that enables them to communicate appropriately in different social contexts. Speakers possess more than just grammatical knowledge. In a multilingual context, for example, interlocutors choose an appropriate code according to context. ‘Context’ includes the relative status of the interlocutors, the purpose of the communication, the respective rights and obligations associated with different language varieties, background knowledge, cultural rules of politeness, etc. This fine-tuning also applies to monolingual societies – this time relating to the choice of style to determine and reinforce the appropriate ‘tenor’ of the interaction. An example comes from the choice of an appropriate second-person pronoun in Hindi: *āp* for formal and respectful usage, *tum* for neutral usage, and *tū* for intimate or disrespectful usage. Such important determinants upon the use of language cannot be relegated to the study of ‘performance’ and hence be excluded from the domain of linguistics as a discipline (as it is within Chomskyan linguistics). Hymes popularized the field of the ‘ethnography of speaking’ within sociolinguistics, drawing upon anthropological traditions of studying speech in its social context and in terms of the value and meaning placed by individual speech communities upon specific speech events. Interactional sociolinguistics, associated with Hymes’s occasional collaborator John Gumperz (e.g., 1982), is a subpart of the study of communicative competence that stresses the dialogic nature of speech. Like Bakhtin, the Russian linguist/critic who wrote in the 1920s to the 1940s, Gumperz insisted that linguistic signs are socially grounded, existing in context-bound encounters between individuals. Social and cultural forces, together with grammar and lexicon, constrain what can be said and how it can be said. An important part of this work concerned the identification of ‘contextualization cues.’ These are constellations of features of the verbal (e.g., vocabulary, prosody, syntactic choices) and nonverbal (e.g., gestures, facial expressions)

configurations, which in the light of previous experience signal what kind of speech activity interlocutors consider themselves to be engaged in (e.g., banter, negotiating a loan, telling a story). The cues help establish social relations, set the frame for what will come next, fill in implicit information, and make inferences about the nature of the speech act. The allied field of 'ethnomethodology' (Garfinkel, 1967) in the social sciences, places such conversational and interactional speech analysis within a wider framework that encompasses all human action, which is seen as reflexively related to the occasions and settings within which it occurs. The focus falls on the perspective of participating members. For ethnomethodologists, the study of members' methods, including all types of practical reasoning and actions, is significant.

'Speech accommodation' is a particular perspective upon the communicative competence that fosters variation in speaker style. Giles and Powesland (1975) held that speakers attune their communicative style in relation to their interlocutor. The basic forms of accommodation are 'convergence' and 'divergence,' depending on the relative status of the speakers and the intended social relations. Bell's (1984) 'audience design' framework elaborated this scheme, taking into account not just the speaker, but the audience (authorized participants, overhearers, eavesdroppers, a displaced mass audience on radio, etc.)

The communicative competence of a speaker might involve proficiency in more than one language co-existing in a society. Whereas Chomskyan syntax focused on an ideal monolingual native speaker, scholars working in multilingual environments have called into question the idea of the native speaker. (As noted in the section above, "Language Is Not a 'Given,'" some scholars have also questioned the very assumption of a prior, well-defined heritable language.) Several commentators have pointed out that such definitions of a native speaker seem to be premised on the norms of monolingual societies, whereas in fact the world is largely multilingual (see Singh, 1998). In some multilingual societies, a child may be said to have several native languages, with the order of acquisition not being an indicator of ability. Multilingual speakers may switch languages according to situation in a way that monolingual speakers switch styles of the same language 'natively' (Scotton, 1985). For many 'New English' speakers, monolingualism is the marked case, a special case outside of the multilingual prototype. Today's ideal speaker lives in a heterogeneous society (stratified along increasingly globalized lines) and has to negotiate interactions with different people representing all sorts of power and solidary positions on a regular basis.

What is this ideal speaker a native speaker of, but a polyphony of codes/languages working cumulatively (and sometimes complementarily), rather than a single, first-learned code?

Studies of code-switching reinforce the notion that communicative competence goes beyond that of the monolingual's mastery of syntax. Accounts of the social and contextual motivations for code-switching have proven a necessary complement to purely structural approaches that seek to account for when in a sentence a speaker may (or may not) switch to another language (Myers-Scotton, 1993). Interaction between speakers, degrees of convergence and divergence, and intentions to alter the rights and obligations associated with one code rather than another have all been fruitfully employed to account for the facility that fluent bilinguals show in switching between languages. 'Crossing' is a particular kind of code-switching in which speakers use a variety that is not generally associated with their group (Rampton, 1995). It permits speakers from one group to overcome social boundaries and build links with members of what may be otherwise seen as an 'outgroup.' Crossing may have an accommodative and emblematic function, but it can also emphasize boundaries if the code used in the crossing reflects stereotypes about the outgroup's language use, rather than their actual practice. Crossing, which is done mainly by adolescents or postadolescents, is one way of calling into question set identities associated with older generations. The notion of identity is crucial in sociolinguistics, in which emphasis falls more on small, self-selected groups or larger groups tied to a regional identity, rather than on national identities.

A 'community of practice' is a collection of people who engage in a common activity on an ongoing basis. The value of the concept, introduced into sociolinguistics by Eckert and McConnell-Ginet (1992), lies in the identification of a social grouping not on the basis of shared abstract characteristics (class, ethnicity etc.) but on the basis of shared practice. The community of practice concept thus mediates between the vernacular (and its basis in early learned, localized forms of language) and official/bureaucratic/transactional language. A focus on the domains of usage and code choice pertaining to those domains necessitates an examination of language in its more bureaucratic modes. The field of language planning deals with the management of language resources of a state or other political entity. A formal language policy may be the outcome of language planning. Language policy may also refer to the norms of the speech community in its characteristic choices of language items or language varieties in relation to some conscious or unconscious ideology. Whereas one

policy or another may have significant influence on the fate of a language, the field of language maintenance and shift shows that language legislation is seldom sufficient to halt the decline of a language. Factors associated with perceived economics and prestige amongst speakers and would-be speakers are equally important.

A fitting though sobering conclusion has to record sociolinguists' involvement in studies of language maintenance and shift in minority communities, and of language endangerment. It is predicted that the vast majority of the world's languages will face a struggle to survive in the present century (Krauss, 1992) as regionally and globally more powerful languages spread. The very cultural and linguistic diversity that sustained small and less powerful communities and that formed the core concerns of sociolinguistics and anthropology is under threat. Recording, cataloguing, archiving, and even teaching languages to communities who have few or no native speakers left have become vital concerns in linguistics.

Applications of Sociolinguistics

There are many practical outcomes of sociolinguistic research, especially in the field of language in education. Sociolinguists have contributed considerably to areas like the home language/school language interface, public debates about less-feted varieties like Ebonics (African American Vernacular English or Black English), an understanding of educational failure, enhancement of gender sensitivity in male-dominated classrooms, and so forth. Sociolinguists provide expert testimony in courtrooms based on their studies of discourse and accent patterns. They also contribute significantly to the growing attempts to save endangered languages and record their heritage, and they cooperate with educationists in government and nongovernment committees on language matters, especially those pertaining to minorities. Sociolinguists also contribute to cultural vitality by recording, describing, and popularizing rural speech and other varieties that are either denigrated or not always recognized as 'legitimate' language. This smooth and holistic interface between theory and application promises health and longevity to a young discipline.

Sociolect/Social Class

R Macaulay, Pitzer College, Claremont, California

Those working in the field of variationist sociolinguistics generally look for some extralinguistic factor that may help to identify features of speech characteristic of groups of speakers. Although all speakers belong to multiple speech communities, four factors have

proved the most durable: age, gender, ethnicity, and social class.

In principle, the easiest social factor to determine is age because at any given time an individual is a certain age, though some people may be reluctant to say what it is. Where precise information is not available, classification into broad categories can usually be estimated on the basis of appearance (Chambers, 1995). It is therefore not surprising that

age regularly appears as an extralinguistic variable in sociolinguistic studies (e.g., Labov, 1963, 1966, 2002; Wolfram, 1969; Fasold, 1972; Trudgill, 1974; Macaulay, 1977; Feagin, 1979; Milroy, 1980; Haeri, 1996; McCafferty, 2001).

However, as Eckert (1997) has pointed out, using age as an extralinguistic variable is not a simple matter. The obvious problem is that age is a continuous variable so that for purposes of correlation with linguistic features, speakers must be classified in age groups. Thus, any use of age as an extralinguistic variable requires a decision about how such age groups are to be identified and justified. Even a simple classification into adults and children is complex, not only because the age at which one can be counted as an adult is itself problematic but also because neither category will be homogeneous.

In comparison to age, gender, seen as a division into male and female, rather than sexual orientation, is relatively simple. Most people are accustomed to declaring their sex/gender in response to many kinds of enquiry and thus this information is usually available to the investigator. Gender is also generally fairly easy to determine on external criteria, although there may be ambiguous cases. Again, it is not surprising that gender is one of the factors frequently examined in sociolinguistic investigations (e.g., Fischer, 1958; Labov, 1966, 2002; Wolfram, 1969; Fasold, 1972; Trudgill, 1974; Macaulay, 1977; Feagin, 1979; Milroy, 1980; Cheshire, 1982; Coupland, 1988; Haeri, 1996; Eckert, 2000; McCafferty, 2001).

Ethnicity is an even more problematic category than gender, not least because it can be determined with reference to a number of characteristics: race, nationality, religion. Any sociolinguistic investigation that includes ethnicity as an extralinguistic category will consequently need to specify clearly how membership in that category is to be established. However, in many situations the population is not ethnically diverse and thus such differences will not be salient in the community.

Social class is perhaps the category that has received the most regular attention from the earliest sociolinguistic studies (e.g., Fischer, 1958; Labov, 1966; Wolfram, 1969; Fasold, 1972; Trudgill, 1974; Macaulay, 1977; Feagin, 1979), and it has continued to be examined in later studies (e.g., Coupland, 1988; Macaulay, 1991, 2005; Haeri, 1996; Foulkes and Docherty, 1999; Labov, 2001; McCafferty, 2001), though it has recently received less consistent attention as a key variable than in earlier studies. However, social class is a much more problematic category than the other three.

Despite receiving considerable attention in recent years by a range of scholars (e.g., see the references

in Crompton *et al.*, 2000), social class remains a controversial subject with many conflicting views. From Lloyd Warner's pioneering studies (Warner, 1949) to Gilbert (2003) in the United States and accounts such as Reid (1989), Argyle (1994), and Cannadine (1998) in Britain, no clear method of identifying social membership has emerged. As Gilbert observes: "there is as much art as science in the study of social stratification" (Gilbert, 2003: 16). For sociolinguists, there is the added problem that the categories identified by sociologists or political scientists may not be the most useful for investigating language variation. Categories that are developed for studying national voting patterns or marketing strategies may not be the most appropriate for examining stratified uses of language in a smaller speech community.

There are two basic questions that are crucial in employing social class as an extralinguistic variable: (1) How many divisions are there within the category of social class? (2) How is membership in any of these divisions to be identified? In response to the first question some investigators (e.g., Fischer, 1958; Trudgill and Foxcroft, 1978; Macaulay, 1991; most contributors to Foulkes and Docherty, 1999; McCafferty, 2001) have treated social class as a dichotomous variable similar to gender with two polarized categories, usually working-class vs. middle-class, or blue-collar workers vs. white-collar workers (Chambers, 1995: 37). Other investigators (e.g., Labov, 1966; Wolfram, 1969; Fasold, 1972; Trudgill, 1974) have treated social class as a continuous variable similar to age and divided the continuum into categories on the basis of certain criteria. Still other investigators (e.g., Macaulay and Trevelyan, 1973; Feagin, 1979; Winford, 1993) have used a judgment sample based on a notion of several discrete social class divisions within the community. Feagin chose a sample that contrasted upper class with working class but also included distinctions according to age (adults over 65 vs. teenagers) and a rural/urban dimension. Winford chose a sample of Trinidadian males on the basis of occupation: middle-class (white-collar workers), upper working class (skilled and semi-skilled workers), and lower working class (unskilled workers and low-paid laborers). The method employed by Macaulay and Trevelyan will be presented below.

The answer to the second question about determining membership in a particular class will differ depending upon the way the sample is chosen. In a judgment sample, the membership in a certain category is determined in advance according to the criteria employed (e.g., occupation, residence). In a random sample, the speakers will also be grouped according to similar criteria, but the linguistic data are

sometimes used to refine this classification, as will be illustrated below.

The answer to both questions will also be affected by the degree to which social class is a salient category in the community. Social stratification may be nearly as universal as language but, like language, social stratification takes different forms in different societies. The extent to which social class differences are a common feature of public discourse will affect the ways in which membership in a particular category can be identified. Cannadine (1998) and Milroy (2004) have pointed out that social class is a much more salient notion in Britain than in the United States.

Argyle (1994) points out that with regard to the situation in Britain: "Part of the evidence that there is a class system is that about 95 per cent of the population think there is, and can say which class they belong to themselves" (Argyle, 1994: 3). Given the desire to use social class as an extralinguistic variable, it is necessary to have some basis on which to choose the sample. Labov (1966) was able to make use of an earlier survey that had been designed by the New York School of Social Work for the Mobilization for Youth survey with a team of 40 interviewers. Probably no other sociolinguist has had such a large randomly chosen sample to work with in a single community.

Labov made use of a 10-point socioeconomic class index developed for the Mobilization for Youth survey by John Michael based on measures of occupation, education, and income. Labov points out that Michael gave "considerable attention to the problem of dividing the continuum of social class" (Labov, 1966: 216), and this was a problem for Labov, too. Labov did not only correlate use of the linguistic variables with speakers from each of the ten points on the scale. Instead, he usually grouped the speakers into three or four social class groups and illustrated the difference this can make (Labov, 1966: 220–248). The most interesting of these is the difference between Labov's figure for the class stratification of the variable (r) (1966: 22, Figure 1) and another figure (1966: 240, Figure 11) for the same variable. In the first, Labov has three groups: 0–2 (the lowest group), 3–5 (the middle group), and 6–9 (the highest group). The three groups show the same stylistic stratification. In the other figure (which is the most frequently cited example of hypercorrection), there are six groups (0, 1, 2–3, 4–5, 6–8, and 9). The separation of 9 from 6–8 shows that the speakers in the latter group use more /r/ in reading aloud word lists and sets of minimal pairs than the speakers in the highest group. This difference was concealed by the grouping used in the first figure. The example illustrates one of

the problems with 'dividing the continuum of social class.' There is clearly a linguistic justification for the grouping in the latter figure, but is there other evidence that the speakers in, for example, category 8 belong with those in categories 6 and 7 rather than with those in category 9? For the (dh) variable (i.e., the use of a stop or an affricate instead of a fricative in words such as *this* and *then*), Labov divides the continuum into three groups: 0–4, 5–6, 7–9. This produces a regular stylistic pattern in a third figure (Labov, 1966: 246, Figure 15). However, from the list of speakers who used either stops or affricates (Labov, 1966: 259, Table 5), there is an argument for dividing the speakers into only two groups 0–4 and 5–9. In the first group, 14 of the 46 speakers (30%) used stops or affricates, in contrast to the second group, in which only 2 of the 35 speakers (6%) used any stops or affricates, a highly significant difference. Later, Labov (1966: 274, Figure 2) shows that educational level accounts for this dichotomy: speakers with less than a 10th-grade education have a much higher frequency of stops and affricates. However, rather than employ the division into two social classes, Labov goes on to develop a four-point social class scale on the basis of education and employment (Labov, 1966: 278) that shows a more regular distribution of the speakers from the lowest social class to the highest in their use of (dh). However, in a re-analysis of Labov's data, Horvath (1985: 64–65) showed that gender was also a powerful determinant of (dh) and better helped to explain the deviant case of Nathan B. (Labov, 1966: 249–253). Chambers (1995: 55–57) points out that the use of fewer non-standard variants of (dh) is an important feature of upwardly mobile speakers, suggesting that this variable is salient for such speakers.

Labov thus presents various arguments for different social class groupings of the speakers, but his questionnaire does not include any question for the speakers about their own view of their class affiliation. Either he did not think it was appropriate, or perhaps he thought his respondents might have difficulty in answering it. However, their answers might have helped to choose between the various groupings rather than depending upon the linguistic analysis to justify the categories. Plausible criteria for identifying social class categories and membership are crucial when social class is employed as one of the extralinguistic variables.

Labov (2001) followed a similar strategy in his later Philadelphia Neighborhood Study. On the basis of education, occupation, and residence value, he developed a 16-point scale which he then divided into six social classes. Labov used regression analysis to tease out the different effects of occupation, education, and residence value on the use of the variables

(2001: 183–186). He concluded that occupation was the most important factor (Labov, 2001: 185). The other factors are perhaps more relevant to notions of social prestige in general than to categories of social stratification. The differences in occupation, however, do not provide a clear answer to the question of how many social classes there are.

It is hard to be sure from Labov's charts (2001: 168–171), but there would appear to be a major difference between his first three groups (the working class groups) and the other three (the middle class and upper class groups). In terms of social class differences, a two-way division would probably have provided clear evidence of the difference between the two. Would this have been a more accurate picture of social class differences in speech than the one that Labov presents? In the absence of any corroborating evidence, it is impossible to tell, but the question is central to an understanding of the relationship between language variation and social class.

Trudgill (1974) also selected a quasi-random sample, from the local register of electors from four of Norwich's electoral wards. Trudgill then developed a social class index on the basis of six separate indicators: occupation, father's occupation, income, education, locality, and housing. One problem with this approach is that each of the indicators is taken to have an equal effect on social class, and that assumption may not be justified (Macaulay, 1976: 185). Like Labov, Trudgill then, on the basis of linguistic data, grouped the scores on the 30-point range into groups that he labeled Middle middle-class, Lower middle-class, Upper working-class, Middle working-class, and Lower working-class. Trudgill was able to show fine stratification in these five categories, but a skeptic looking at his results might wonder whether the separation of the working-class speakers into three categories is justified. Like Labov, Trudgill did not ask his speakers about social class or where they would put themselves.

Labov's and Trudgill's methods are worth examining closely because they are scrupulously honest and make it quite clear how they arrived at their categories. However, they also illustrate the difficulties that sociolinguists face in employing categories such as social class. It is not enough to choose a way of dividing up the sample into discrete groups; there has to be some reason to believe that these groups correspond to actual social divisions. Those who have not employed multiple indices have usually taken occupation as the main criterion for membership of a particular social class (e.g., Macaulay, 1977; Coupland, 1988; McCafferty, 2001), but some investigators have used place of residence (e.g., Stuart-Smith, 1999). Such criteria, however, are no guarantee that

the resulting categories correspond to actual social classes.

When I was planning my work in Glasgow (Macaulay and Trevelyan, 1973; Macaulay, 1977), the most recent work on Scottish society was Kellas (1968) in which it was suggested that there were three major social class divisions in Scotland, based on occupation. In adopting this classification, I modified it, splitting Kellas's middle category by separating manual workers from non-manual. This gave four social class groups: I, IIa, IIb, III. The Registrar-General's list of occupations provided a guide to membership in each of these categories. I used these categories to identify a judgment sample of speakers, balanced for gender and age (10-year-olds, 15-year-olds, and adults), and the use of five linguistic variables was correlated with these categories. On the basis of the results of the analysis, it became obvious that there were no significant differences between groups IIb and III. In other words, the difference between manual (IIb and III) and non-manual (IIa) workers proved important. Thus, like Labov and Trudgill, I modified my classification on the basis of the linguistic data.

As part of the interview, I had included questions for the adult speakers about the number of social class categories in the city and where they would place themselves. Their responses were consistent with the notion of a three-part division (Macaulay, 1976) that matched the results of the linguistic analysis. However, it also appeared that there was no clear label for those who fell between the polarized groups of working-class and middle-class. As one woman put it:

Well I wouldn't call myself middle-class but on the other hand I would call myself middling. In other words, I'm not up there and I'm not down there. I just reckon I'm pretty average. [Macaulay, 1977: 63]

This speaker sees the middle-class as being 'up there' and the working-class as being 'down there,' but she does not have a simple label for people like herself who are 'pretty average.' This comment illustrates the danger of taking a label such as 'middle-class' literally. The Class I speakers also resisted the suggestion that they were 'upper class', although they admitted that they belonged to the upper stratum of Glasgow society.

Responses such as this one and others collected in the Glasgow survey (Macaulay, 1976) show that even when social class divisions are salient in the society, there may not be an adequate public language in which to label the differences. Nevertheless, the kind of subjective opinions elicited in the Glasgow survey can be useful in identifying how the speakers

themselves perceive the critical social class divisions in a society. Perhaps investigators carrying out large-scale sociolinguistic surveys could incorporate some of the methods of perceptual dialectology (Preston, 2002).

There is, however, little evidence that many investigators are planning large-scale surveys of specific communities in which social class differences might be significant in accounting for language variation. A preoccupation with linguistic change has perhaps deflected attention from wider goals. This is unfortunate because social class differences are obviously important in predicting educational achievement, and language skills are fundamental to success in the school system. More attention by sociolinguists to aspects of language variation other than pronunciation might be helpful in educational planning.

Given the complexity of dealing with social class, some investigators have followed the example of the Milroys (Milroy and Milroy, 1978; Milroy, 1980) in using social networks as the basis for examining language variation. Social networks are “personal communities which provide a meaningful framework for solving the problems of daily life” (Milroy, 2001: 550). A network approach “provides a set of procedures for studying small groups where speakers are not discriminable in terms of any kind of social class index” (Milroy, 2001: 556).

A similar kind of approach is to examine a community of practice. “A community of practice is an aggregate of people who come together around mutual engagement in an endeavor” (Eckert and McConnell-Ginet, 1992). Eckert (2000) demonstrates the value of this approach in her study of high school students in Detroit. The difference between a social network and a community of practice is not simply one of size, though networks have the potentiality to be much larger than communities of practice. One important difference is that an individual ‘may belong to or participate in a number of different communities of practice’ (Meyerhoff, 2001: 531), while individuals will rarely belong to numerous social networks.

Social networks and communities of practice provide an alternative basis for approaching language variation, but they do not replace the larger notions of age, gender, ethnicity, and social class, because individuals will still have these characteristics. However, all four categories interact in complex ways (Eckert, 2003; Macaulay, 2005) and thus generalizations about the effect of one factor may be misleading without taking the others into consideration. For this reason, claims about social class differences in language should always be carefully examined for possible sources of bias and the empirical basis for the claims. For example, it is not always

made clear that Basil Bernstein’s wide-ranging claims about social class differences in Britain (Bernstein, 1962) were based on small samples of speech from ten middle-class boys and fourteen working-class boys, aged between 15 and 18, recorded under inadequate conditions of control (Macaulay, 2005).

Despite the problems, social class has been shown to be related to variation in many aspects of language. It is not possible here to review all the work that has been done in many parts of the world, but some illustrative examples will suggest the range of investigation. The majority of studies have dealt with phonological variables. Differences in vowel quality have been found to correlate with social class differences in a number of studies (e.g., Labov, 1966, 2001; Trudgill, 1974; Macaulay, 1977, 1991; McCafferty, 2001), but interestingly more robust correlations have often been found for consonants (e.g., Labov, 1966; Wolfram, 1969; Trudgill, 1974; Macaulay, 1977; Coupland, 1988; Milroy *et al.*, 1994; McCafferty, 2001). This may be because consonantal variables are often stable sociolinguistic features, though the recent spread of glottal stops in Britain is an obvious exception. Social class differences in intonation have not been investigated systematically, but that may change with developments in instrumental techniques of measurement. Stuart-Smith (1999) has examined social class differences in voice quality in Glasgow. She found that working-class Glaswegian voice quality had more open jaw, raised and backed tongue body with possible retracted tongue root, and whispery voice. She observes that middle-class Glaswegian voice quality “is best described in terms of the *absence* of WC traits” (Stuart-Smith, 1999: 215).

In morphology, social class differences have been found in tense marking (e.g., Wolfram, 1969; Fasold, 1972; Feagin, 1969; Macaulay, 1991). Social class differences in forms of negation have also been found in widely different communities (e.g., Wolfram, 1969; Feagin, 1979; Macaulay, 1991). With regard to modality, Feagin (1979) showed that there were social class differences in the use of double modals (e.g., *she might could be a big help to you*) and the quasi-modal *liketa* (e.g., *she liketa had a heart attack!*) in Anniston, Alabama. Thibault (1991) identified social class differences in the use of *devoir* as a modal in Montreal. Winford (1993) found social class differences in the use of perfect *have* in Trinidadian English.

A small-scale study showed social class differences in the use relative pronouns in Ayr (Macaulay, 1991) with the middle-class speakers much more likely to use *wh*-relatives. In a longitudinal study of Montreal French, Blondeau (2001) found that simple non-clitic pronouns (e.g., *nous* vs. *nous autres*) were more

common in the upper levels of the social scale in Montreal. In another Montreal study, Dubois (1992) described social class differences in the use of extension particles with the professional class more likely to use forms such as *et cetera* while the working-class speakers preferred forms such as *patati patata*. Macaulay (2001) showed that in Ayr and Glasgow, working-class speakers used significantly fewer derived adverbs and intensifiers such as *very* than the middle-class speakers.

In a study of discourse variation in a sample of Glasgow adolescents and adults, Macaulay (2005) found that three-quarters of the 32 discourse features examined showed no social class differences. In addition to the differences in adverbs and relative pronouns mentioned above, the working-class speakers used more modal auxiliaries and more dislocated syntax, such as clefting or right and left dislocation (e.g., *Mr. Patterson he was a gentleman*). The middle-class speakers used more passives and more evaluative adjectives, as well as the hedge *sort of*. The lack of more significant differences led to the conclusion:

Despite important differences in education, income, and place of residence, the Glasgow speakers use language for the most part in very similar ways. (Macaulay, 2005: 157)

This point perhaps needs emphasizing in any account of language variation. While age, gender, ethnic, and social class differences in language are of interest and may often be socially important, these differences are small in comparison with what the speakers have in common with each other.

Sociolinguistics and Political Economy

M Bucholtz, University of California, Santa Barbara, CA, USA

Since the beginnings of sociolinguistics, it has been well established that language and economic structures are interrelated. Other social sciences concerned with political economy have been largely dismissive of language, viewing it as an entirely symbolic rather than material phenomenon. By contrast, sociolinguists – including both those who describe and those who critique capitalist systems – have repeatedly and conclusively demonstrated that language is intimately tied to speakers' material economic position.

The earliest work examining this relationship concentrated on the linguistic dimensions of social class, particularly the social and economic reflexes of the standard and the vernacular forms of a language. The robust correlations that variationist sociolinguists found between socioeconomic status and language use were cited as powerful evidence of the social organization of linguistic variation. Variationist sociolinguistics was also instrumental in redirecting scholarship on speakers living in poverty from a framework centering on language deficiencies to one focused on linguistic difference.

Whereas the first studies of language and social class were largely framed within a structural-functionalist paradigm in which social classes orient to the same social norms, and in which class organization is consensual, scholars informed by Marxist theory have argued that a conflict-based model of class would improve the fit between sociolinguistic findings and the social theories used to account for them, insofar as language is used not only in parallel fashion across classes but also to carve out social differences between classes. The difficulties of objectively

determining class led other researchers to focus on social networks, in which occupation figured heavily, as a way of arriving at locally meaningful social groupings for linguistic analysis.

Social class has been at the center of a longstanding debate in sociolinguistics: how to account for the widespread pattern in which women are frequently found to surpass men in the use of standard variables. One early explanation for this pattern was that women, lacking equal access to real-world power, use language as a symbolic resource to claim social prestige by projecting through their speech a class position above their actual material circumstances. A revised version of this argument posits that women more than men are socially evaluated not on their accomplishments but on their personhood, and that language is a crucial component of self-presentation. This account allows for the possibility (which has been empirically demonstrated in variationist-sociolinguistic research) that some female speakers might seek to project a working-class rather than middle-class persona and hence will outpace their male counterparts in the use of vernacular rather than standard variables.

This analysis of the semiotic power of language relies heavily on the work of Pierre Bourdieu, a central theorist in sociolinguistic discussions of political economy. For Bourdieu, language is a form of capital, a term that for him includes not only economic power but also social, cultural, and symbolic power. Bourdieu argues that when a linguistic market is constituted in a society, the distribution of linguistic capital – that is, the form of the language imbued with the most power within the market – is uneven across speakers. The economic analogy is not wholly metaphorical, for Bourdieu notes that power in the linguistic marketplace tends to extend to power in the economic marketplace as well. However, language can function as a primarily symbolic form of capital

that enables speakers to accrue local prestige, such as popularity among high school students in the United States, although even in this situation speakers' choice of linguistic variables tends to correlate with their orientation to socioeconomically divergent pathways after high school: jobs versus college.

The relationship between language and work, which has long informed variationist sociolinguistic research, has also been explored within other paradigms. Ethnographic sociolinguists have documented the ways in which opportunities in the labor market are tied to language, demonstrating not only that lack of access to linguistic capital prevents economic mobility, but also that even within a limited field of options speakers may make agentive and strategic linguistic choices to promote their own social goals, whether these involve economic advancement or participation within a local linguistic and economic market. Although scholarship on standardization, language shift and loss, and the international spread of English has shown that broad political-economic forces such as nationalism, colonialism, industrialization, and globalization have dramatic and often catastrophic consequences for language, such research also demonstrates that these forces cannot fully determine speakers' linguistic practices.

In contrast to much of the work on language and economic systems discussed above, which considers the linguistic consequences of broad economic structures and processes, research within discourse analysis considers the details of language use within specific economic contexts. A body of literature in several subfields has examined a wealth of issues regarding language in the workplace. Interactional sociolinguists, concerned with how cultural differences in interactional style may lead to misunderstandings and conflicts between interlocutors in culturally diverse work settings, seek to document the pragmatics of talk among coworkers and between service providers and customers or clients. Scholars working in the traditions of interactional sociolinguistics, conversation analysis, critical discourse analysis, and other approaches have also given extensive attention to language use in institutional settings such as medical contexts, the legal system, the educational system, and the media, in which issues of power and economic access are centrally relevant. And as both multilingual linguistic competence and friendly, facilitative interactional practices have emerged as marketable skills within the postindustrial service economy, scholars have begun to document the ways in which the linguistic abilities of a diverse workforce come to be shaped to the needs of late capitalism.

Although socioeconomic structures and institutional contexts have been the aspects of economic

systems most central to sociolinguistic research, another crucial element of economic processes, consumption, has begun to gain ground. The relationship between language and consumer culture has been of deep interest particularly within critical discourse analysis and other politically oriented sociolinguistic frameworks. Focusing on advertising discourse, popular media textual products such as mass-market fiction and television shows, and other commodified forms of discourse, this body of work offers a critical perspective on how members of the public are transformed into consumers. However, research is still greatly needed on how people both at the center and on the periphery of consumer culture use language to make sense of such texts and of other aspects of consumption in their daily lives.

Related to this issue is the phenomenon of commodified language – language that functions not only as labor but as a product for consumption. Such commodification is most vividly seen in the appropriation of symbolically laden languages and dialects in advertising, mass media, and popular culture to enhance corporate profits, but it is also evident in the promotion of talk as a valued object in its own right in all aspects of late capitalist society, as seen in the marketing of verbal intimacy from psychotherapy to phone sex to coffeehouse conversations.

Many other arenas of language and political economy are only recently being explored by sociolinguists, particularly within newly industrializing societies and those most dramatically reshaped by globalization. Indeed, it is not an overstatement to assert that every aspect of sociolinguistics touches on political-economic issues. As those working in the many branches of the field continue to pursue their diverse research agendas, scholarship will benefit greatly from deeper and more extensive attention to this powerful and pervasive aspect of sociolinguistic life.

Speech Accommodation Theory and Audience Design

A Bell, Auckland University of Technology, Auckland, New Zealand

Accommodation theory is an approach to language style developed by the social psychologist Howard Giles and associates since the 1970s. Accommodation is “the adjustment of one’s speech or other communicative behaviours *vis-à-vis* the people with whom one is interacting” (Giles, 2001). Initially called Speech Accommodation Theory (SAT), it was broadened in the 1980s to encompass wider aspects of interaction under the label of Communication Accommodation Theory (CAT).

In its early stages accommodation theory was concerned with the causes and consequences of the convergence or divergence of speech styles. The model proposed that speakers accommodate their speech to their addressee in order to win their approval (Giles and Powesland, 1975). This means that the common form of accommodation is convergence, by which speakers shift their style of speech to become more like that of their addressees. A range of experiments (e.g., Giles and Smith, 1979) demonstrated how speakers converge with other each other on a number of levels such as speech rate, accent, content, and pausing. Studies have shown that convergence tends to be positively evaluated by recipients, being registered as a desire for social integration, identification, and approval. Giles, Taylor, and Bourhis (1973) found that in the bilingual context of Montreal, the amount of effort a speaker was perceived to have made in language choice between French and English affected how highly they were evaluated.

Classically, convergence occurs when a speaker intends to converge; linguistic analysis shows that this has indeed occurred; and the psychological climate of the interaction is one of interpersonal association (Giles, 2001). Convergences have been categorized under various distinctions, usually binary. A convergence may be upward or downward, depending on the relative social status of the interlocutors; full or partial, depending on how far a speaker moves toward her interlocutor; symmetrical or asymmetrical, depending whether the shift is unilateral or not.

Alternatively, instead of converging, speakers may maintain their style of speech or even diverge from their addressee. Divergence is regarded as a tactic of intergroup distinctiveness, by which individuals or groups differentiate themselves from other individuals or groups. As later studies have shown, however, there is no automatic interpretation of the meaning

of convergence, as it can in some circumstances be construed as psychological divergence.

The social psychological aspect of accommodation theory became increasingly complex as it tried to encompass facts such as these that do not sit easily with simple convergence or divergence. The theory originally suggested that the greater the desire for approval, the greater would be the convergence. Some early experiments (e.g., Street, 1982) do show that. However, Giles and Smith (1979) found that speakers can converge too much, causing addressees to react unfavorably to what they may feel is patronizing or ingratiating behavior. Conversely, addressees need not always disapprove of divergence.

Riders to the theory have proliferated, especially in the comprehensive refinements by Thakerar *et al.* (1982), Coupland *et al.* (1988), and Giles *et al.* (1991). Thakerar *et al.*’s (1982) three-dimensional model of accommodation allows for a complex range of options and remains a core statement of the sociopsychological foundation of the theory. They introduced a distinction between psychological and linguistic accommodation, including the possibility that a speaker may converge linguistically while diverging psychologically.

Coupland *et al.* (1988) expanded accommodation to a wider set of attuning strategies, specifically in health- and age-related communication, by which communicative dimensions other than language are accommodated to a speaker’s perceptions of an interlocutor. Giles *et al.* (1991) explored the distinctions that have been made in accommodation theory, providing a detailed historical view of the development of the theory to that time. Further aspects of convergence and divergence are characterized, including uni- versus multimodal and subjective versus objective accommodation. They acknowledge the possibility that, given the multiplicity of linguistic and extralinguistic features involved in any interaction, a speaker may converge in some features and diverge in others.

The weight of accommodation theory’s apparatus thus expanded in the 1980s to cover the more nuanced findings that were emerging through empirical work. Elaboration of the theory has not extended greatly since then, doubtless in part because the models had already become very complex and not easily capable of further refinement. However, the basic insights of accommodation remain sound: that speakers accommodate their style to their audience. If we understand accommodation encompassing any style shift that occurs in response to an audience, the theory is a powerful explanatory model of style.

It goes beyond the descriptive taxonomy and non-directional correlation in earlier sociolinguistic approaches to propose an explanation of what causes style shift. Shepard *et al.* (2001) provide a review of accommodation studies to the end of the 20th century. Contemporary research continues to use the accommodation framework as an approach to a variety of sociolinguistic issues such as gender-related accommodation by children (Robertson and Murachver, 2003) and accommodation in intergenerational communication (Williams and Garrett, 2002).

To linguists, early accommodation theory's chief deficiency was its linguistic naïveté, dealing largely in quasilinguistic parameters such as speech rate or utterance length, or intentionally unsophisticated ratings of whole accents. By the 1980s some sociolinguists came to accommodation theory to explain the patterns they were finding in their study of specific linguistic features. Conversely, both social psychologists (e.g., Giles, 1973) and sociolinguists (e.g., Bell, 1984; Coupland, 1984) had critiqued the accepted Labovian paradigm (1966) that held that style was controlled by the amount of attention paid to speech. Major studies by Bell (1982) and Coupland (1984) were early examples of a more fine-grained sociolinguistic analysis that utilized the insights of accommodation theory (see also Trudgill, 1981).

The most widespread approach to style in sociolinguistics (Eckert and Rickford, 2001) has been audience design, which has close parallels to accommodation theory, but arose disciplinarily from (socio)linguistics rather than social psychology. Developed by Bell (1984), who derived the term from Clark (Clark and Carlson, 1982), audience design proposes that speakers' style choices are primarily a response to their audience. The framework has been summarized (Bell, 1997, 2001) under nine headings:

1. Style is what an individual speaker does with a language in relation to other people. Style is essentially interactive and social, marking interpersonal and intergroup relations.
2. Style derives its meaning from the association of linguistic features with particular social groups. The social evaluation of a group is transferred to the linguistic features associated with that group. Styles carry social meanings through their derivation from the language of particular groups.
3. The core of audience design is that speakers design their style primarily for and in response to their audience. Audience design is generally manifested in a speaker shifting her style to be more like that of the person she is talking to – convergence, in terms of accommodation theory.

4. Audience design applies to all codes and levels of a language repertoire, monolingual and multilingual.
5. Variation on the style dimension within the speech of a single speaker derives from and echoes the variation that exists between speakers on the social dimension. This axiom claims that quantitative style differences are normally less than differences between social groups.
6. Speakers show a fine-grained ability to design their style for a range of different addressees, and to a lessening degree for other audience members such as auditors and overhearers.
7. Style shifts according to topic or setting derive their meaning and direction of shift from the underlying association of topics or settings with typical audience members.
8. As well as the responsive dimension of style, there is the initiative dimension, where a style shift itself initiates a change in the situation rather than results from such a change. Sociolinguists have drawn attention to this distinction at least since Blom and Gumperz's (1972) proposal of situational versus metaphorical styles. In responsive style shift, there is a regular association between language and social situation. Initiative style trades on such associations, infusing the flavor of one setting into a different context, in what Bakhtin (1981) has called 'stylization.' Language becomes an independent variable that shapes the situation.
9. Initiative style shifts are in essence referee design, by which the linguistic features associated with a group can be used to express affiliation with that group. They focus on an absent reference group rather than the present audience. This typically occurs in the performance of a language or variety other than one's own (cf. Rampton's concept of crossing, 1995).

Audience design has been applied in detail as a framework by, for example, Rickford and McNair-Knox (1994) in their study of style shifting by an African American teenager. It has also been contested on a variety of grounds – the priority it gives to social variation over style (Finegan and Biber, 1994), its disregard of the role of attention to speech (Labov, 2001), and in particular, its inadequate attention to the active, constitutive role of language in interaction (Coupland, 2001; Schilling-Estes, 2004). Later developments in audience design (e.g., Bell, 2001) have countered by stressing the proactive nature of language style in identity formation and presentation. Responsive and initiative style are treated as different but concurrent dimensions of language usage, manifesting the structure/agency duality familiar in

social theory. This accords both with the stress in contemporary social theory on language as constitutive, and with the dialogical theory of Bakhtin (1981). The range of linguistic analysis in audience design has also been increasingly extended to include qualitative and cooccurrence analyses as well as quantification (Bell, 1999).

The state-of-the-art reader edited by Eckert and Rickford (2001) brings together a wide range of contributions on accommodation theory, audience design, and other sociolinguistic approaches to style. Subsequent work (e.g., Coupland, 2001; Schilling-Estes, 2004) combines strengths from different approaches, including audience design and accommodation theory.

Definition and Terminology

The term ‘speech act verbs’ has variously been defined as applying either to all verbs used to refer to any type of verbal behavior or to the much smaller subset of verbs expressing specific speaker attitudes. According to the first, more encompassing definition, verbs such as *to claim*, *to promise*, *to threaten*, *to praise*, *to boast*, *to complain*, *to say*, *to whisper*, and *to interrupt* all count as speech act verbs, whereas the last three of this set are excluded by the second and stricter definition. The terms ‘illocutionary verbs,’ ‘verbs of communication,’ and ‘verbs of saying,’ which have been used as synonyms of ‘speech act verbs,’ have likewise been defined in either a more or less inclusive fashion. Because verbs such as *to say*, *to whisper*, and *to interrupt* do not lexicalize speaker attitudes, they are semantically less specific than speech act verbs in the narrow sense of the term. For this reason, this contribution is concerned only with speech act verbs that lexicalize combinations of speaker attitudes.

Speech act verbs are used to refer to situations characterized by the following features or situational roles: a speaker (S), a hearer (H), a set of speaker attitudes, and an utterance (Utt) mostly containing a proposition (P). These four elements are part of any situation referred to by speech act verbs and constitute the unifying feature of the meaning of these verbs (Verschueren, 1980: 51–57; 1985: 39–40; Wierzbicka, 1987: 18; Harras *et al.*, 2004: Intro.). They distinguish them from other elements of the lexicon, especially from other types of verbs. Adopting the terminology used by Harras *et al.* (2004) here I call the type of situation referred to by all speech act verbs the ‘general resource situation type.’ Special types of situations referred to by speech act verbs are called ‘special resource situation types.’

Classes of Speech Act Verbs

Special resource situation types constitute the framework for the classification of different types of speech act verbs. They are built up from specifications of the role of the utterance and of the speaker attitudes, which are both elements of the general resource situation type. The set of speaker attitudes may be specified as consisting of the speaker’s attitude to the

proposition, the speaker’s intention, and the speaker’s presuppositions. The speaker’s propositional attitude may be further specified as S’s taking P to be true, S’s wanting P, S’s evaluating P positively or negatively, and so on. Specifications of the speaker’s intention include S’s intention to make H believe something or to get him/her to do something. Examples of specifications of the speaker’s presuppositions are S’s presupposition that H does not know P, that H will do P in the normal course of events, and that H is able to do P. The role of the utterance is specified by properties of the propositional content. These include the event type of P (that is, whether P is an action, event, or state of affairs), the agent of P (in the case that P is an action), and the temporal reference of P (specifically, whether P precedes, coincides with, or follows S’s uttering P).

Figure 1 shows the different types of specifications of each of the elements of the general resource situation type. Following a procedure proposed by Baumgärtner (1977: 260–264), the specifications in Figure 1 are obtained from a comparison of sentences containing speech act verbs. The well-formedness of some of these and the ill-formedness of others shows which elements are relevant to the meaning of the verbs they contain. For example, a comparison of the sentences *I order you to leave the room*, **I order you to have left the room*, and **I order you for me to leave the room* shows that *to order* lexicalizes the specification ‘future action of H’ for the properties of the propositional content.

Different combinations of specifications of the different kinds of speaker attitudes and of the properties of the propositional content constitute special resource situation types, which are referred to by distinct types of speech act verbs. The combinations listed in Table 1 represent situations that are referred to by specific types of verbs. Elements of the situations referred to are also components of the meaning of the corresponding verbs. If the assertives and information verbs in Table 1 are subsumed under the larger class of representatives and verbs expressing emotions are grouped together with those expressing evaluations, all speech act verbs in Table 1 may be classified as belonging to one of four main classes: representatives, directives, commissives, and expressives. These correspond to four of the main types of speech acts distinguished by Searle (1975: 354–361). In addition, there exists a fifth class of verbs that may be used to refer to speech acts, which Searle called ‘declarations.’ These are speech acts in which a particular institutional fact is brought about by a speaker who has the authority to do so because he or she is a representative of

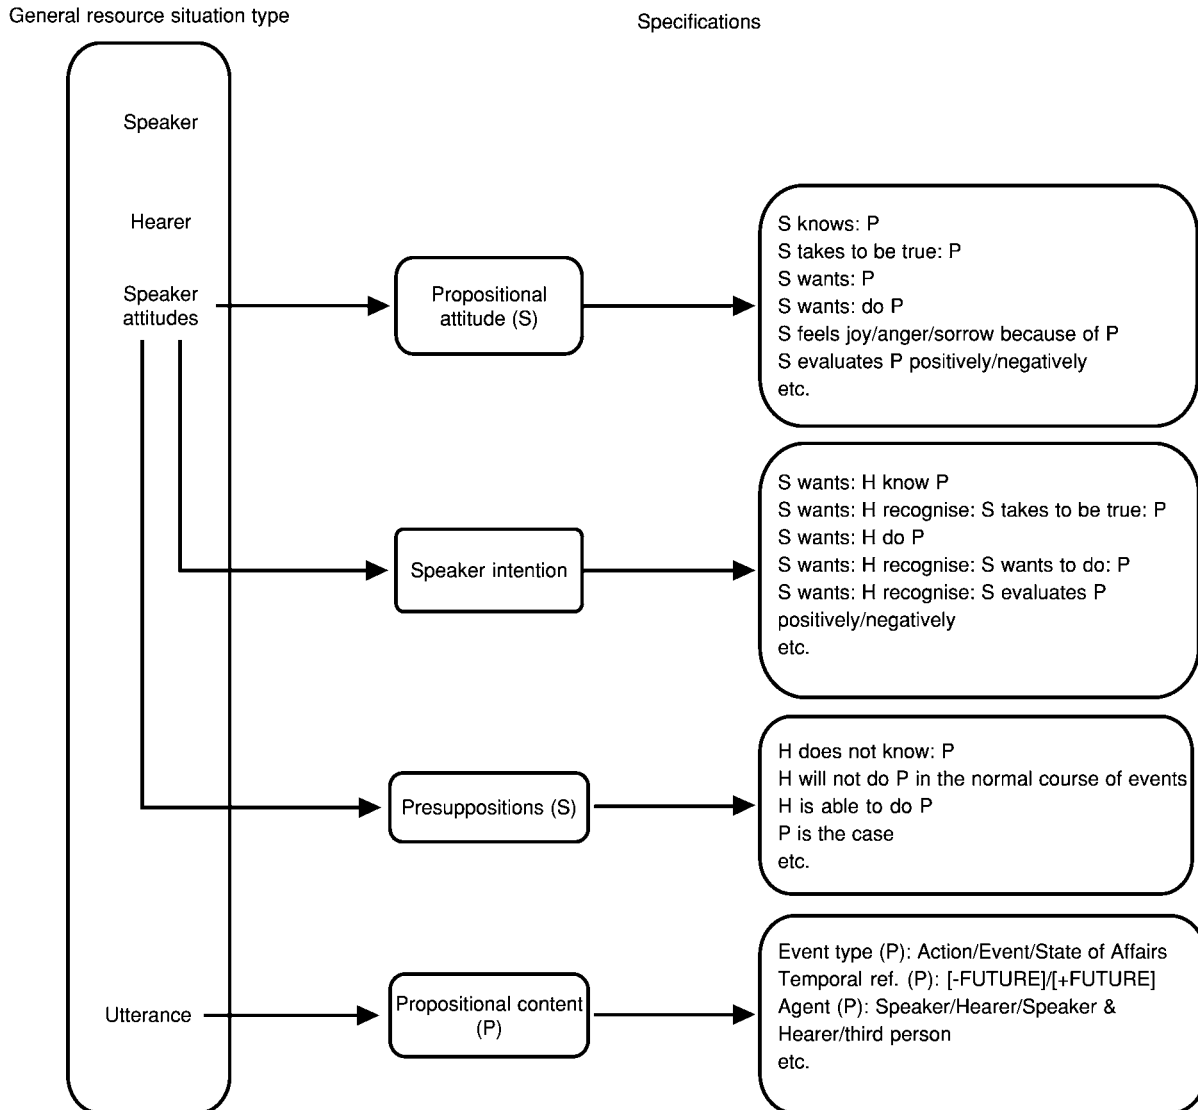

Figure 1 Specification of the elements of the general resource situation type.

a particular institution. The performance of declarations does not involve any particular speaker attitudes apart from the speaker's being willing to bring about the relevant institutional fact. Accordingly, declaratives, that is verbs used to refer to declarations, differ from other kinds of speech act verbs in that they lexicalize no speaker attitudes other than the speaker's intention to bring about a particular institutional fact. Examples of declaratives include *to absolve*, *to baptize*, *to bequeath*, *to condemn*, *to excommunicate*, *to fire*, *to nominate*, and *to resign*.

Other classifications have much in common with Searle's taxonomy. Austin's (1962: 150–163) classification of speech act verbs, for example, comprises five classes (expositives, exercitives, commissives, behabitives, and verdictives, which approximately correspond to Searle's representatives, directives,

commissives, expressives, and declarations, respectively). Vendler's classification was based on Austin's. Due to the fact that Vendler distinguished two types of exercitives (interrogatives and genuine exercitives) as well as two types of verdictives (operatives and true verdictives), his classification consists of seven rather than five classes (Vendler, 1972: 16–25). Bach and Harnish divided speech acts into six general categories. Four of these (constatives, directives, commissives, and acknowledgements) "correspond roughly to Austin's expositives, exercitives, commissives and behabitives respectively, and closely to Searle's representatives, directives, commissives and expressives" (Bach and Harnish, 1979: 40–41). Taken together, the remaining two classes, effectives and verdictives, correspond to what Searle called "declarations." Using H's evaluations as criteria,

Table 1 Classes of speech act verbs

(1a)	Assertives: <i>claim, assert . . .</i> , Propositional attitude (S):	S takes to be true: P
	Intention (S):	S wants: H recognize: S takes to be true: P
	Presupposition (S):	H does not know: P
	Event type (P):	Action/Event/State of Affairs
	Temporal reference (P):	[-FUTURE]/[+ FUTURE]
(1b)	Information Verbs: <i>inform, tell, impart, communicate, etc.</i> Propositional attitude (S):	S knows: P
	Intention (S):	S wants: H know: P
	Presupposition (S):	H does not know: P
	Event type (P):	Action/Event/State of Affairs
	Temporal reference (P):	[-FUTURE]/[+ FUTURE]
(2)	Directives: <i>ask (sb. to do sth.), order, request . . .</i> , Propositional attitude (S):	S wants: P
	Intention (S):	S wants: H do P
	Presupposition (S):	H will not do P in the normal course of events
	Event type (P):	H is able to do P
	Agent (P):	Action
(3)	Commissives: <i>promise, guarantee, pledge, vow . . .</i> , Propositional attitude (S):	Hearer
	Intention (S):	[+ FUTURE]
	Presupposition (S):	S wants to do P
	Event type (P):	S wants: H recognise: S wants to do P
	Agent (P):	P is in the interest of H
(4a)	Verbs Expressing Emotions: <i>rejoice, complain, scold . . .</i> , Propositional attitude (S):	Action
	Intention (S):	Speaker
	Presupposition (S):	[+ FUTURE]
	Event type (P):	S feels joy/anger/sorrow because of P
	Temporal reference (P):	S wants: H recognise: S feels joy/anger/sorrow because of P
(4b)	Verbs Expressing Evaluations: <i>praise, criticise . . .</i> , Propositional attitude (S):	P is the case
	Intention (S):	Action/Event/State of Affairs
	Presupposition (S):	[-FUTURE]
	Event type (P):	S evaluates P positively/negatively
	Agent (P):	S wants: H recognise: S evaluates P positively/negatively
	Temporal reference (P):	P is the case
		Action
		Hearer or Third Person

Allan (1994: 4125; 1998: 10–11) distinguished four types of speech acts. Statements include speech acts such as denials, reports, and predictions (Searle's representatives) as well as promises and offers (Searle's commissives). Invitationals are a subset of Searle's directives and include speech acts such as requests, suggestions, exhortations, and warnings. The rest of Searle's directives are grouped together with his declarations into a class called 'authoritatives.' Expressives, finally, include greetings, thanks, apologies, and congratulations. Table 2 compares the classifications discussed.

Speech Acts and Speech Act Verbs

The examples considered so far suggest that the meanings of speech act verbs may be described in terms of

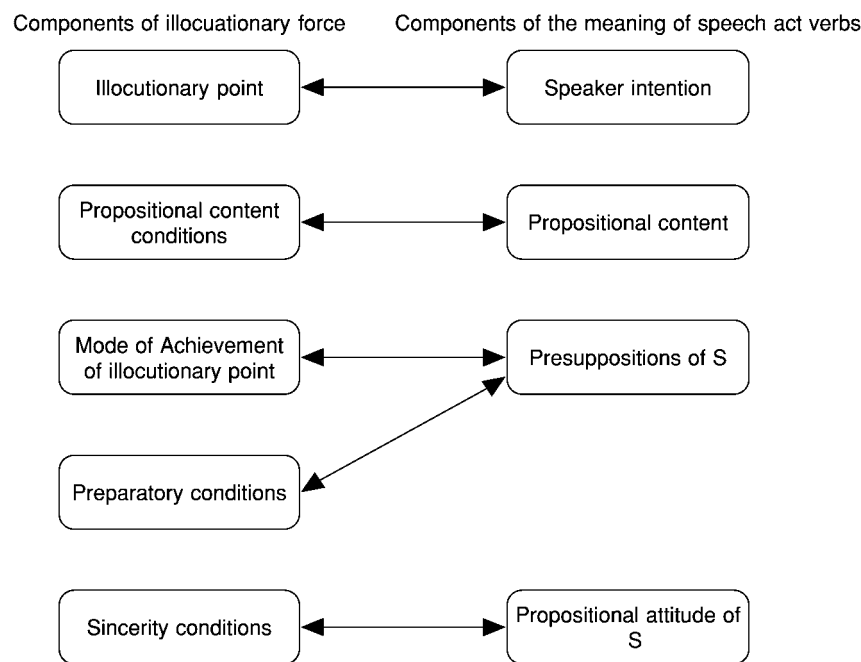

properties of speech acts. The components of speech acts and those of speech act verbs do indeed display substantial overlap. This may be observed from the fact that the components of the meanings of speech act verbs correspond to at least five of the seven components of illocutionary force that serve to determine under which conditions a particular type of speech act is both successful and nondefective (Searle and Vanderveken, 1985: 12–20). These correspondences are summarized in Figure 2.

In spite of these correspondences, special resource situation types do not suffice to capture the meaning of all speech act verbs. Examples of verbs whose meanings cannot completely be described in terms of elements of special resource situation types are *boast*, *flatter*, and *lie*. In addition to the attitudes of a resource situation speaker, these verbs lexicalize

Table 2 Different types of classifications of speech acts/speech act verbs

different types of evaluations by a speaker who uses these verbs to describe the speech act of the resource situation speaker. Following Barwise and Perry (1983: 32–39), here I call the situation in which a speaker describes an act performed by a resource situation speaker the ‘discourse situation.’ As **Figure 3** shows, the discourse situation comprises the same types of elements as the resource situation: a speaker, a hearer, and an utterance containing a proposition. The meaning of verbs such as *boast*, *flatter*, and *lie* comprises elements of a resource as well as a discourse situation. For example, *boast* lexicalizes not only a positive evaluation of P (one of S’s own actions or properties) by the speaker of the resource situation but also a negative evaluation of the resource situation speaker’s

positive representation of P by a discourse situation speaker. In particular, a discourse situation speaker describing a resource situation speaker’s act of self-praise by means of the verb *boast* thereby indicates that he or she considers the resource situation speaker’s positive representation of P to be exaggerated. Similarly, *flatter* and *lie* lexicalize a combination of attitudes of a resource situation speaker as well as a discourse situation speaker’s evaluation of the speech act performed by the resource situation speaker as being strategic (*flatter*) or insincere (*lie*). These examples show that for many illocutionary verbs, there is no corresponding speech act. Nor may any type of speech act be referred to by a corresponding illocutionary verb. An example is the apparent lack of a

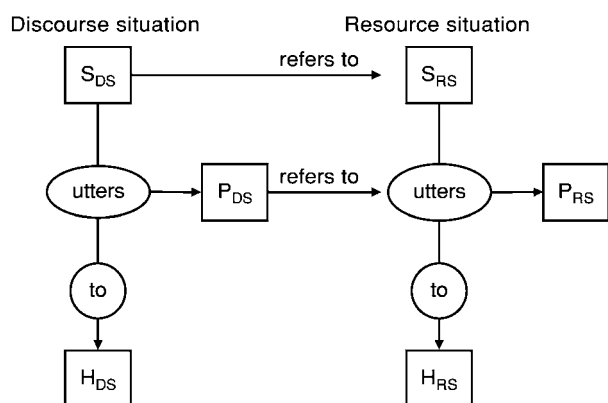

Figure 3 The inventory of situational roles of the discourse and the resource situation (S_{DS} , discourse situation speaker; S_{RS} , resource situation speaker; P_{DS} , proposition uttered by S_{DS} ; P_{RS} , proposition uttered by S_{RS} ; H_{DS} , discourse situation hearer; H_{RS} , resource situation hearer). From Harras *et al.* (2004: 10); used with permission of Walter de Gruyter, GmbH. & Co.

special illocutionary verb in English to refer to an act in which a speaker predicts a future event that he or she considers to have negative consequences. Although there are special illocutionary verbs to describe such acts in German (e.g., *unken*) and Russian (e.g., *karkat*), the relevant act has to be referred to in English by less specific verbs such *predict*, *foretell*, and *prophecy*, whose meanings do not include an evaluative component.

The lack of a one-to-one correspondence of speech acts and speech act verbs also becomes evident from the fact that some verbs are systematically ambiguous among several illocutionary points (Vanderveken, 1990: 168). For example, *to promise* may be used to refer to acts of threatening (as in *I promised him that he would be punished if he did not come back in time*), acts of promising (as in *I promised to help him*), and acts of assuring somebody of something (as in *I promised her that she would be free tomorrow* uttered by a speaker who is not the agent of P but only a confident news bearer). Other examples are *warn* and *advise*, which may both be classified as being either representatives (verbs used to denote an act of telling somebody that something is the case) or directives (verbs used to refer to an act of telling somebody to do something to avoid an imminent danger) (Searle and Vanderveken, 1985: 183). In spite of Austin's claim that speech act verbs are a good guide to speech acts (Austin 1962: 148–149), the absence of a one-to-one correspondence between speech acts and speech act verbs indicates that differences in the meaning of speech act verbs are “a good guide but by no means a sure guide to differences in illocutionary acts” (Searle, 1975: 345).

Performativity

Some speech act verbs can be used not only to denote but also to perform a particular speech act. To test whether a given speech act verb may be used in this way, Austin suggested that it be substituted for the variable x in the formula ‘I (hereby) $x \dots$ ’. Any verb that may be used as a part of this formula may be used performatively (Austin, 1962: 67). Examples of performative verbs are *to order*, *to promise*, *to inform*, *to criticize*, and *to assert*. The performative formula is often part of the institutionalized procedure by which a speaker brings about a particular institutional fact. Consequently, declaratives may generally be used performatively as in *I hereby name this ship the ‘Queen Elisabeth’* and *I appoint you chairman*. Other types of speech act verbs can be used performatively only if they may be used in utterances that do not require an additional linguistic or nonlinguistic action for a particular speech act to be performed. For example, a speaker may promise a hearer to help him or her solely by uttering a sentence such as *I promise to help you tomorrow*. By contrast, an act of convincing somebody that something is the case requires more than a speaker's uttering a sentence such as *?I convince you that Beowulf is the single most important work of English literature*. This difference accounts for the fact that *to promise* may be used performatively, whereas *to convince* may not (Harras 2004: 152–154).

Speech Acts

Y Huang, University of Auckland, Auckland, NZ

© 2006 Elsevier Ltd. All rights reserved.

Speech act theory, though foreshadowed by the Austrian philosopher Ludwig Wittgenstein's views about language-games (see **Wittgenstein, Ludwig Josef Johann**), is usually attributed to the Oxford philosopher J. L. Austin (see **Austin, John L.**). The basic ideas, which were formed by him in the late 1930s, were presented in his lectures given at Oxford in 1952–1954, and later in his William James Lectures delivered at Harvard in 1955. These lectures were finally published posthumously as *How to do things with words* in 1962. After his death in 1960, Austin's ideas were refined, systematized, and advanced, especially by his Oxford pupil, the American philosopher John R. Searle. Simply stated, the central tenet of speech act theory is that the uttering of a sentence is, or is part of, an action within the framework of social institutions and conventions. Put in slogan form, saying is (part of) doing, or words are (part of) deeds.

J. L. Austin

The Performative/Constative Dichotomy

In the 1930s, a very influential school of thought in philosophy was logical positivism, developed by a group of philosophers and mathematicians principally in Vienna. One of the central doctrines of logical positivism is what is now called 'the descriptive fallacy,' namely, the view that the only philosophically interesting function of language is that of making true or false statements. A particular version of the descriptive fallacy is the verificationist thesis of meaning, namely, the idea that 'unless a sentence can, at least in principle, be verified (i.e., tested for its truth or falsity), it was strictly speaking meaningless'

(Levinson, 1983: 227). On such a view, sentences that are not used to make verifiable or falsifiable propositions are simply meaningless.

It was against this philosophical background that Austin set about to develop his theory of speech acts (Austin, 1962). He made two important observations. First, he noted that some ordinary language sentences such as those in (1) are not employed to make a statement, and as such they cannot be said to be true or false.

- (1a) Good afternoon!
- (1b) Is he a Republican?
- (1c) Come in, please.

Secondly and more importantly, Austin observed that there are ordinary language declarative sentences that similarly resist a truth-conditional analysis. The point of uttering such sentences is not just to say things, but also actively to do things. In other words, such utterances have both a descriptive and an effective aspect. Accordingly, Austin called them 'performatives,' and he distinguished them from assertions, or statement-making utterances, which he called 'constatives.' In other words, performatives are utterances that are used to do things or perform acts, as in (2), whereas constatives are utterances that are employed to make assertions or statements, as in (3).

- (2a) I christen/name this ship the Princess Elizabeth.
- (2b) I now pronounce you man/husband and wife.
- (2c) I promise to come to your talk tomorrow afternoon.
- (3a) My daughter is called Elizabeth.
- (3b) A freshly baked loaf doesn't cut easily.
- (3c) Maurice Garin won the first Tour de France in 1903.

Unlike those in (3), the declarative sentences in (2) have two characteristics: (i) they are not used intentionally to say anything, true or false, about states of affairs in the outside world, and (ii) their

use constitutes (part of) an action, viz., that of christening/naming a ship in (2a), that of pronouncing a couple married in (2b), and that of promising in (2c). In addition, there are two further differences between (2a–b) and (2c). The first is that while (2a–b) is part of a conventional or ritual behavior supported by institutional facts (see also Strawson, 1964), (2c) is not. Secondly, while the performative verb, that is, the verb naming the action while performing it in (2a–b) is in general an essential element and cannot be omitted, it can in (2c). In other words, whereas, for example, we cannot christen/name a ship without using the verb *christen* or *name*, we can make a promise without using the verb *promise*, as in (4).

(4) I'll come to your talk tomorrow afternoon.

Performatives can further be divided into two types: explicit and implicit. Explicit performatives are performative utterances that contain a performative verb that makes explicit what kind of act is being performed. By contrast, implicit performatives are performative utterances in which there is no such verb. Thus, the performatives in (2) are explicit ones, and the performative in (4) is an implicit one.

Austin also isolated a number of syntactic and semantic properties of explicit performatives in English: (i) explicit performatives contain a performative verb, (ii) the performative nature of such a verb can be reinforced by adding the adverb *hereby*, and (iii) explicit performatives occur in sentences with a first-person singular subject of a predicate (verb) in the simple present tense, indicative mood, and active voice.

However, as Austin himself was aware, there are exceptions. Explicit performatives can sometimes take a first-person plural subject, as in (5); a second-person singular or plural subject, as in (6); and a third-person singular or plural subject, as in (7). In addition, there are cases where the explicit performative verb is 'impersonal,' that is, it does not refer to the speaker, as in (8). Furthermore, as (6), (7), and (8) show, explicit performatives can occur in sentences where the verb is in the passive voice. Finally, as (9) indicates, they can also occur in sentences of present progressive aspect.

- (5) We suggest that you give up smoking immediately.
- (6) You are fired.
- (7) Passengers are hereby requested to wear a seat belt.
- (8) Notice is hereby given that shoplifters will be prosecuted.
- (9) I am warning you not to dance on the table.

Austin's Felicity Conditions on Performatives

As already mentioned, it makes no sense to call a performative true or false. Nevertheless, Austin noticed that for a performative to be successful or 'felicitous,' it must meet a set of conditions. For example, one such condition for the speech act of naming is that the speaker be recognized by his or her community as having the authority to perform that act; for the speech act of ordering, the condition is that the speaker have authority over the addressee; and finally, for the speech act of promising, one condition is that what is promised by the speaker must be something the addressee wants to happen. Austin called these conditions 'felicity conditions,' of which he distinguished three types, as shown in (10).

- (10) Austin's felicity conditions on performatives
 - (10a) (i) There must be a conventional procedure having a conventional effect.
 - (10a) (ii) The circumstances and persons must be appropriate, as specified in the procedure.
 - (10b) The procedure must be executed (i) correctly and (ii) completely.
 - (10c) Often
 - (i) the persons must have the requisite thoughts, feelings and intentions, as specified in the procedure, and
 - (ii) if consequent conduct is specified, then the relevant parties must so do.

Violation of any of the conditions in (10) will render a performative 'unhappy' or infelicitous. If conditions *a* or *b* are not observed, then what Austin described as a 'misfire' takes place. For instance, in England, a registrar conducting a marriage ceremony in an unauthorized place will violate condition *a* (i), thus committing a misfire. The same is true for a clergyman baptizing the wrong baby, because in this case, condition *a* (ii) is not fulfilled. Next, as an illustration of a violation of condition *b* (i), consider the case of a bridegroom not saying the exact words that are conventionally laid down for a Church of England marriage ceremony. As to condition *b* (ii), it dictates that the procedure be complete. Thus, in making a bet, the bet is not 'on' unless *You are on* (or something with the same effect) is uttered by the addressee; in Austin's terminology, this counts as a satisfactory 'uptake,' the absence of which will again cause a misfire. Finally, if condition *c* is violated, then what Austin called an 'abuse' is committed (including, but not only, cases of insincerity). Examples include: congratulating someone when one knows that he or she passed his or her examination by cheating (condition *c* (i)); making a promise when one already intends to break it (condition *c* (ii)); and marrying without intending to consummate the marriage

(see also Sadock's (2004) discussion of these conditions in terms of misinvocation, misexecution, and abuse).

Locutionary, Illocutionary, and Perlocutionary Speech Acts

The initial distinction made by Austin between performatives and constatives was soon to be rejected by him in favor of a general theory of speech acts. In fact, as pointed by Levinson (1983: 231), there are two internal shifts in Austin's arguments. First, there is a shift from the view that performatives are a special class of sentences/utterances with peculiar syntactic and semantic properties to the view that there is a general class of performatives that encompasses both explicit and implicit performatives, the latter including many other types of sentences/utterances. The second shift is from the performative/constative dichotomy to a general theory of speech acts, of which the various performatives and constatives are just special sub-cases (*see Speech Acts and Grammar*).

What led Austin to abandon the performative/constative dichotomy? In the first place, he noted that like performatives, constatives are also subject to the felicity conditions stated in (10). Consider the so-called 'Moore's paradox,' illustrated by (11).

- (11) ?Princess Diana died in a fatal car crash in Paris with Dodi Al Fayed, but I don't believe it.

This utterance is infelicitous because it violates condition *c* (i) in (10) above. In the same vein, if someone utters (12) when he or she knows that John does not in fact have a wife, then its presupposition will not go through. The reason the presupposition fails to carry through is that condition *a* (ii) in (10) above is not adhered to.

- (12) I'm sure John's wife is a feminist.

Secondly, Austin observed that performatives and constatives may be impossible to distinguish even in truth-conditional terms. On the one hand, there are 'loose' constatives that may not be assessed strictly by means of truth conditions, as in (13). On the other hand, there are utterances like those in (14) that pass the *hereby* test and therefore are performatives by definition but that nevertheless are used to state or assert. In these cases, the performatives must be counted simultaneously as constatives. On the basis of such evidence, Austin concluded that constatives are nothing but a special class of performatives, and that the two-way distinction between performatives, as action-performers, and constatives, as truth-bearers, can no longer be maintained.

- (13a) France is hexagonal.
 (13b) The fridge is empty.
 (13c) New York is sixty miles from where I live.
 (14a) I hereby state that Da Vinci started to paint *Mona Lisa* in 1503.
 (14b) I hereby tell you that the bill is right.
 (14c) I hereby hypothesize that there is water on Mars.

Consequently, Austin claimed that all utterances, in addition to meaning whatever they mean, perform specific acts via the specific communicative force of an utterance. Furthermore, he introduced a three-fold distinction among the acts one simultaneously performs when saying something, as illustrated in (15):

- (15) (A speech act's three facets)
 (i) Locutionary act: the production of a meaningful linguistic expression.
 (ii) Illocutionary act: the action intended to be performed by a speaker in uttering a linguistic expression, by virtue of the conventional force associated with it, either explicitly or implicitly.
 (iii) Perlocutionary act: the bringing about of consequences or effects on the audience through the uttering of a linguistic expression, such consequences or effects being special to the circumstances of utterance.

A locutionary act is the basic act of speaking, which itself consists of three related sub-acts: (i) a phonic act of producing an utterance-inscription; (ii) a phatic act of composing a particular linguistic expression in a particular language; and (iii) a rhetoric act of contextualizing the utterance-inscription (Austin, 1962). The first of these three sub-acts is concerned with the physical act of producing a certain sequence of vocal sounds (in the case of spoken language), or a set of written symbols (in the case of written language). The second refers to the act of constructing a well-formed string of sounds/symbols (a word, phrase, or sentence in a particular language). The third sub-act is responsible for tasks such as assigning reference, resolving deixis, and disambiguating the utterance-inscription lexically and/or grammatically (*see Deixis and Anaphora: Pragmatic Approaches*).

The illocutionary act refers to the fact that when we say something, we usually say it with some purpose in mind. In other words, an illocutionary act refers to the type of function the speaker intends to fulfill, or the action the speaker intends to accomplish in the course of producing an utterance; it is also an act defined within a system of social conventions. In short, it is an act accomplished in speaking. Examples of illocutionary acts include accusing, apologizing, blaming, congratulating, declaring war, giving

permission, joking, marrying, nagging, naming, promising, ordering, refusing, swearing, and thanking. The functions or actions just mentioned are also commonly referred to as the illocutionary 'force' (or 'point') of the utterance. Illocutionary force is frequently conveyed by what Searle (1969) called an 'illocutionary force indicating device' (IFID), the most direct and conventional type of which is an explicit performative in the form of (16) (where Vp stands for performative verb). Indeed, the term 'speech act' in its narrow sense is often taken to refer exclusively to illocutionary acts (*see Speech Acts, Classification and Definition*).

(16) I (hereby) Vp you (that) S

It should be mentioned at this point that the same linguistic expression can be used to carry out a wide variety of different speech acts, so that the same locutionary act can count as having different illocutionary forces in different contexts. Depending on the circumstances, one may utter (17) to make a threat, to issue a warning, or to give an explanation.

(17) The gun is loaded.

In fact, Alston (1994) has argued that the meaning of a sentence consists in its having a certain illocutionary act potential (IAP) that is closely and conventionally associated with its form. On this view, to know what a sentence means is to know what range of illocutionary acts it can be conventionally used to perform.

Conversely, the same speech act can be performed by different linguistic expressions, or the same illocutionary force can be realized by means of different locutionary acts. The utterances in (18), for example, illustrate different ways of carrying out the same speech act of requesting.

(18) (At ticket office in railway station)

(18a) A day return ticket to
Oxford, please.

(18b) Can I have a day return ticket to
Oxford, please?

(18c) I'd like a day return ticket to Oxford.

Finally, a perlocutionary act concerns the effect an utterance may have on the addressee. Put slightly more technically, a perlocution is the act by which the illocution produces a certain effect in or exerts a certain influence on the addressee. Still another way to put it is that a perlocutionary act represents a consequence or by-product of speaking, whether intentional or not. The effect of the act being performed by speaking is generally known as the perlocutionary effect. There is an extensive literature on the differentiation between locutionary, illocutionary, and perlocutionary acts (*see e.g., Sadock (2004) for a survey*).

J. R. Searle

Searle's Felicity Conditions on Speech Acts

Just as its truth conditions must be met by the world for a sentence to be said to be true, its felicity conditions must also be fulfilled by the world for a speech act to be said to be felicitous. Searle (1969) took the view that the felicity conditions put forward by Austin are not only ways in which a speech act can be appropriate or inappropriate, but that they also jointly constitute the illocutionary force. Put in a different way, the felicity conditions are the constitutive rules – rules that create the activity itself – of speech acts (*see Principles and Rules*). On Searle's view, to perform a speech act is to obey certain conventional rules that are constitutive of that type of act. Searle developed the original Austinian felicity conditions into a neo-Austinian classification of four basic categories, namely (i) propositional content, (ii) preparatory condition, (iii) sincerity condition, and (iv) essential condition. As an illustration of these conditions, consider (19).

- (19) Searle's felicity conditions for promising
- (i) propositional content: future act A of S
 - (ii) preparatory: (a) H would prefer S's doing A to his not doing A, and S so believes
 - (b) It is not obvious to both S and H that S will do A in the normal course of events
 - (iii) sincerity: S intends to do A
 - (iv) essential: the utterance of e counts as an undertaking to do A

where S stands for the speaker, H for the hearer, A for the action, and e for the linguistic expression.

The propositional content condition is in essence concerned with what the speech act is about. That is, it has to do with specifying the restrictions on the content of what remains as the 'core' of the utterance (i.e., Searle's propositional act) after the illocutionary act part is removed. For a promise, the propositional content is to predicate some future act of the speaker, whereas the preparatory conditions state the real-world prerequisites for the speech act. In the case of a promise, the latter are roughly that the addressee would prefer the promised action to be accomplished, that the speaker knows this, but also that it is clear to both the speaker and the addressee that what is promised will not happen in the normal course of action. Next, the sincerity condition must be satisfied if the act is to be performed sincerely. When carrying out an act of promising, the speaker must genuinely intend to keep the promise. Notice that if the sincerity condition is not fulfilled, the act is still performed, but there is an abuse, to use Austin's term. Finally, the essential condition defines the act being performed in

the sense that the speaker has the intention that his or her utterance will count as an act, and that this intention is recognized by the addressee. Thus for a promise, the speaker must have the intention to create an obligation to act. Failure to meet the essential condition has the consequence that the act has not been carried out.

Searle's Typology of Speech Acts

Can speech acts be classified, and if so, how? Austin (1962) grouped them into five types: (i) *verdictives*: giving a verdict, (ii) *exercitives*: exercising power, rights or influence, (iii) *commissives*: promising or otherwise undertaking, (iv) *behabitives*: showing attitudes and social behavior, and (v) *expositives*: fitting an utterance into the course of an argument or conversation. Since then, there have been many attempts to systematize, strengthen, and develop the original Austinian taxonomy (Bach and Harnish, 1979; Allan, 2001; Bach, 2004). Some of these new classifications are formulated in formal/grammatical terms, others, in semantic/pragmatic terms, and still others, on the basis of the combined formal/grammatical and semantic/pragmatic modes (see Sadock (2004) for a review) (*see Speech Acts, Classification and Definition; Pragmatics: Overview*). Of all these (older and newer) schemes, Searle's (1975a) neo-Austinian typology remains the most influential. Under Searle's taxonomy, speech acts are universally grouped into five types along four dimensions: (i) illocutionary point, (ii) direction of fit between words and world, (iii) expressed psychological state, and (iv) propositional content (see also Searle (2002)). The five types of speech acts are further explained next.

(i) *Representatives* (or *assertives*; the *constatives* of the original Austinian performative/constative dichotomy) are those kinds of speech acts that commit the speaker to the truth of the expressed proposition and thus carry a truth-value. They express the speaker's belief. Paradigmatic cases include asserting, claiming, concluding, reporting, and stating. In performing this type of speech act, the speaker represents the world as he or she believes it is, thus making the words fit the world of belief.

(20) The Berlin Wall came down in 1989.

(ii) *Directives* are those kinds of speech acts that represent attempts by the speaker to get the addressee to do something. They express the speaker's desire/wish for the addressee to do something. Paradigmatic cases include advice, commands, orders, questions, and requests. In using a directive, the speaker intends to elicit some future course of action on the part of the

addressee, thus making the world match the words via the addressee.

(21) Put the cake in the oven.

(iii) *Commissives* are those kinds of speech acts that commit the speaker to some future course of action. They express the speaker's intention to do something. Paradigmatic cases include offers, pledges, promises, refusals, and threats. In the case of a commissive, the world is adapted to the words via the speaker himself.

(22) I'll never buy you another computer game.

(iv) *Expressives* are those kinds of speech acts that express a psychological attitude or state of the speaker such as joy, sorrow, and likes/dislikes. Paradigmatic cases include apologizing, blaming, congratulating, praising, and thanking. There is no direction of fit for this type of speech act.

(23) Well done, Elizabeth!

(v) *Declarations* (or *declaratives*) are those kinds of speech acts that effect immediate changes in some current state of affairs. Because they tend to rely on elaborate extralinguistic institutions for their successful performance, they may be called institutionalized performatives. In performing this type of speech act, the speaker brings about changes in the world; that is, he or she effects a correspondence between the propositional content and the world. Paradigmatic cases include (officially) opening a bridge, declaring war, excommunicating, firing from employment, and nominating a candidate. As to the direction of fit, it is both words-to-world and world-to-words.

(24) I object, Your Honor.

Illocutionary point (or speech act type), direction of fit, and expressed psychological state can be summarized as in (25).

(25) Illocutionary point/Speech act type	Direction of fit	Expressed psychological state
representative	words-to-world	belief
directive	world-to-words	desire
commissive	world-to-words	intension
expressive	none	variable
declaration	both	none

Indirect Speech Acts

What is an indirect speech act? Most of the world's languages have three basic sentence types: declarative, interrogative, and imperative. In some languages, the three major sentence types are distinguished morphologically and/or syntactically; as instances,

compare Somali, Greenlandic, or Lakhota (Lakota) (see Huang (2006) for further discussion). The three sentence types are typically associated with the three basic illocutionary forces, namely, asserting/stating, asking/questioning, and ordering/requesting, respectively.

In the case of a direct match between a sentence type and an illocutionary force, we have a direct speech act. In addition, explicit performatives, which happen to be in the declarative form, are also taken to be direct speech acts, because they have their illocutionary force explicitly named by the performative verb in the main part (or 'matrix clause') of the sentence. On the other hand, if there is no direct relationship between a sentence type and an illocutionary force, we are faced with an indirect speech act. Thus, when an explicit performative is used to make a request, as in (26), it functions as a direct speech act; the same is the case when an imperative is employed, as in (27). By comparison, when an interrogative is used to make a request, as in (28), we have an indirect speech act.

(26) I request you to pass the salt.

(27) Pass the salt.

(28) Can you pass the salt?

In short, the validity of the distinction between direct and indirect speech acts is dependent upon whether or not one subscribes to what Levinson (1983: 264, 274) has called the 'literal force hypothesis' – the view that there is a direct structure-function correlation in speech acts and that sentence forms are direct reflexes of their underlying illocutionary forces.

There are, however, problems at the very heart of the literal force hypothesis. One is that there are cases of speech acts where even the direct link between performative verbs and speech acts breaks down. Consider (29).

(29) I promise to sack you if you don't finish the job by this weekend.

In (29), the performative verb is *promise*, but the force that is most naturally ascribed to this speech act is that of either a threat or a warning. This shows that, contrary to the literal force hypothesis, we cannot always identify speech acts, even with sentences containing a performative verb.

Secondly and more importantly, as also pointed out by Levinson (1983: 264), most usages are indirect. The speech act of requesting, for example, is very rarely performed by means of an imperative in English. Instead, it is standardly carried out indirectly. Furthermore, there are probably infinitely many

varieties of sentences that can be used to indirectly make a request, as shown in (30).

(30a) I want you to put the cake in the oven.

(30b) Can you put the cake in the oven?

(30c) Will you put the cake in the oven?

(30d) Would you put the cake in the oven?

(30e) Would you mind putting the cake in the oven?

(30f) You ought to put the cake in the oven.

(30g) May I ask you to put the cake in the oven?

(30h) I wonder if you'd mind putting the cake in the oven?

As to how to analyze indirect speech acts, there are roughly three approaches. The first is to assume the existence of a dual illocutionary force (as proposed by Searle, 1975b). On this assumption, indirect speech acts have two illocutionary forces, one literal or direct, and the other nonliteral or indirect. While the literal force is secondary, the nonliteral force is primary. Next, whether an utterance operates as an indirect speech act or not has to do with the relevant felicity conditions. For example, (28) both infringes the felicity condition for a question and queries the preparatory condition for a request. This explains why it can function as an indirect speech act, whereas (31), for instance, cannot; the reason is that in the case of (31), felicity conditions are irrelevant.

(31) Salt is made of sodium chloride.

Finally, on Searle's view, because a speaker's performing and an addressee's understanding an indirect speech act always involves some kind of inference, the question is how this inference can be computed. Searle's suggestion is that it can be computed along the general lines of the rational, cooperative model of communication articulated by Grice (1989) (see Grice, Herbert Paul; Cooperative Principle).

One interesting characteristic of indirect speech acts is that they are frequently conventionalized (see, e.g., Morgan, 1978). This can be illustrated by the fact that of various, apparently synonymous linguistic expressions, only one may conventionally be used to convey an indirect speech act, as illustrated in (32).

(32a) Are you able to pass the salt?

(32b) Do you have the ability to pass the salt?

Under Searle's analysis, both (32a) and (32b) would be expected to be able to perform the indirect speech act of requesting, because (i) they are largely synonymous with (28), and (ii) they, too, inquire about the satisfaction of the addressee-based preparatory condition for making a request. But this expectation is not fulfilled.

Searle's response to this puzzle is that there is also a certain degree of conventionality about indirect speech acts, and that this may be accounted for in terms of conventions of meaning/usage. Inspired by this insight, Morgan (1978) developed the notion of 'short-circuited implicature' to cover inference involved in cases like (28) (see **Implicature**). While the relevant implicature is in principle calculable, in practice it is not calculated in cases like these. From a linguistic point of view, the conventionality here is correlated with the possible occurrence of *please*. While *please* can be inserted before the verb *pass* in (26)–(28), it cannot in (32), as shown in (33).

- (33a) I request you to please pass the salt.
- (33b) Please pass the salt.
- (33c) Can you please pass the salt?
- (33d) ?Are you able to please pass the salt?
- (33e) ?Do you have the ability to please pass the salt?

Furthermore, the conventionality indicated by *please* in (33a) and (33b) is one of meaning, hence the speech act of requesting is performed directly. By contrast, the conventionality signaled by *please* in (33c) is one of usage, and thus we have an indirect speech act.

A second, rather similar, approach is due to Gordon and Lakoff (1975). In their analysis, there are inference rules called 'conversational postulates' that reduce the amount of inference needed to interpret an indirect speech act. Thus, in the case of (28), if the interpretation as a question cannot be intended by the speaker, then the utterance will be read as being equivalent to his or her having said (26), thus resulting in the performance of the indirect speech act of requesting. Stated this way, the conversational postulates proposed by Gordon and Lakoff can be seen as another reflection of the conventionality of indirect speech acts. As to the similarities and differences between Searle's and Gordon and Lakoff's analyses, the major similarity is that both accounts assume that the interpretation of indirect speech acts involves inference as well as conventionality; the major difference concerns the question of balance, namely, how much of the work involved in computing an indirect speech act is inferential and how much is conventional.

Finally, in contrast to the inferential models we have just discussed, there is the idiom model. In this model, sentences like (28) are semantically ambiguous, and the request interpretation constitutes a speech act idiom that involves no inference at all. On this view, (28) is simply recognized as a request, with no question being perceived. This is the position taken by Sadock (1974). There are, however, problems with this analysis, too. One is that it fails to

capture the fact that (in contrast to what is the case for idioms) the meaning of an indirect speech act can frequently (at least in part) be derived from the meaning of its components (the technical term for this is 'compositionality'; see Frege, Friedrich Ludwig Gottlob); in addition, these would-be 'idioms' turn out to be quite comparable cross-linguistically (something which idioms are not). For example, an utterance like (34) may be used, with the same force as in English, in its Arabic, Chinese, German, or Modern Greek versions to indirectly request the addressee to switch on the central heating system (of course, always depending on the context).

- (34) 'It's cold in here.'

A further problem is that in the idiom model, an interpretation that takes into account the literal meaning or the direct illocutionary force of an indirect speech act is not allowed. This, however, leaves examples like (35) unexplained.

- (35) A: Can you pass the salt?
B: Yes, I can. (Here it is.)

Why, then, do people use indirect speech acts? One answer is that the use of indirect speech acts is in general associated with politeness. Indirect speech acts are usually considered to be more polite than their direct counterparts (see the considerable literature on the analysis of speech acts, especially the work on face-threatening acts (FTAs) like requests, complaints, and apologies in the tradition of Brown and Levinson's (1987) classical 'face-saving' politeness model see **Face; Politeness; Pragmatic Acts**).

Speech Acts and Culture

Cross-Cultural Variation

Many speech acts are culture-specific. This is particularly so in the case of institutionalized speech acts, which typically use standardized and stereotyped formulae and are performed in public ceremonies. A good example is provided by the speech act of divorcing. In some Muslim cultures, under the appropriate circumstances, the uttering of a sentence with the import of (36) three times consecutively by a husband to his wife will *ipso facto* constitute a divorce. By contrast, in Western cultures, no one (no matter what his or her religion is) can felicitously use (36) to obtain a divorce.

- (36) 'I hereby divorce you.'

But how about non-institutionalized speech acts? First of all, as said above, any given speech act may be culture-specific. Rosaldo (1982), for example,

observed that the speech act of promising has no place among the Ilongots – a tribal group of hunters and horticulturalists in the Philippines. She attributes the absence of this speech act in the conceptual repertoire of the Ilongot to a lack of interest in sincerity and truth in that community. The Ilongot, argues Rosaldo, are more concerned with social relationships than with personal intentions. On the basis of anthropological evidence such as this, Rosaldo claims that the universality of Searle's typology of speech acts cannot be maintained. Another example of this kind has been reported for the Australian aboriginal language Yolngu. According to Harris (1984: 134–135), there does not seem to be any speech act of thanking in the Yolngu speaker's repertoire.

Conversely, a given speech act may be present only in certain cultures. For example, in the Australian aboriginal language Walmajari, one finds a speech act of requesting that is based on kinship rights and obligations. The verb in question is *japirlyung* (Hudson, 1985), and the speech act may be called 'kinship-based requesting,' because it conveys a message meaning roughly 'I ask/request you to do X for me, and I expect you to do it simply because of how you are related to me'. Thus, for the speakers of Walmajari, it is very difficult to refuse a kinship-based speech act of requesting (see also Wierzbicka, 1991: 159–160). 'Exotic' speech acts such as the kinship-based requesting do not seem to be present in other East Asian or Western cultures.

Secondly, given a particular situation, pertinent speech acts are carried out differently in different cultures. For instance, in some East Asian and Western cultures, if one steps on another person's toes, one normally performs the speech act of apologizing. But apparently this is not the case among the Akans, a West African culture. As reported by Mey (2001: 287, crediting Felix Ameka), in that culture, such a situation does not call for apologies but calls for the expression of sympathy: "The focus is on the person to whom the bad thing has happened rather than the person who has caused the bad thing" (Mey, 2001: 287). Another example: while in English, thanks and compliments are usually offered to the hosts when leaving a dinner party, in Japanese society, apologies such as *o-jama itashimashita* 'I have intruded on you' are more likely to be offered by the guests. A similar speech act of apologizing is performed in Japanese upon receiving a present, when a Japanese speaker is likely to say something like *sumimasen* – the most common Japanese 'apology' formula or one of its variants. Conversely (as pointed out by many authors), apologies can be used in a much broader range of speech situations in Japanese than in English.

Thirdly, in different cultures/languages, the same speech act may meet with different typical responses. For example, a compliment normally generates acceptance/thanking in English, but self-denigration in Chinese, Japanese, or even Polish. A typical compliment/response formula in Chinese would be something like (37).

- (37) A: ni cai zuode zhen hao!
 B: nali, nali, wo bu hui zuocai.
 A: bie keqi. ni cai zhende zuode hen hao!
 B: ni tai keqi le.
 A: 'You cook really well!'
 B: 'No, no, I don't really know how to cook properly.'
 A: 'Please don't be too modest. You really cook very well.'
 B: 'You're too kind.'

The same is even more true in Japanese. According to Mizutani and Mizutani (1987: 43), "[T]he Japanese will never accept a compliment without saying *ie* ['no']". Given the general Japanese reluctance to say 'no' under almost any other circumstances, the compliment response pattern is rather striking.

Fourthly, the same speech act may differ in its directness/indirectness in different cultures. Since the late 1970s, a great deal of research has been conducted on how particular kinds of speech acts, especially such face-threatening acts as requests, apologies, and complaints are realized across different languages (see Face). Of these investigations, the most influential is the large-scale Cross-Cultural Speech Act Realization Patterns Project (CCSARP) (Blum-Kulka *et al.*, 1989). In this project, the realization patterns of requesting and apologizing in German; Hebrew; Danish; Canadian French; Argentinean Spanish; and British, American, and Australian English were compared and contrasted. In the case of requests, the findings were that among the languages examined, the Argentinean Spanish speakers are the most direct, followed by the speakers of Hebrew. The least direct are the Australian English speakers, while the speakers of Canadian French and German are positioned at the midpoint of the directness/indirectness continuum. Building on the CCSARP, strategies for the performance of certain types of face-threatening acts in a much wider range of languages have since been examined. These languages include Catalan, Chinese, Danish, Dutch, French, German, Greek, Hebrew, Japanese, Javanese, Polish, Russian, Thai, Turkish, four varieties of English (British, American, Australian, and New Zealand), two varieties of French (Canadian and French), and eight varieties of Spanish (Argentinean, Ecuadorian, Mexican, Peninsular,

Peruvian, Puerto Rican, Uruguayan, and Venezuelan). As a result of these studies, it has now been established that there is indeed extensive cross-cultural variation in directness/indirectness in speech acting, especially in the realization of face-threatening acts (FTAs), and that these differences are generally associated with the different means that different languages utilize to realize speech acts (see **Intercultural Pragmatics and Communication**). These findings have undoubtedly contributed to our better understanding of cross-cultural/linguistic similarities and differences in face-redressive strategies for FTAs (see Huang (2006) for detailed discussion).

Interlanguage Variation

A number of studies have recently appeared that explore speech acts in interlanguage pragmatics. Simply put, an interlanguage is a stage on a continuum within a rule-governed language system that is developed by L2 learners on the way to acquiring the target language. This language system is intermediate between the learner's native language and his or her target language.

Some of these studies investigate how a particular type of speech act is performed by non-native speakers in a given interlanguage; others compare and contrast the similarities and differences in the realization patterns of given speech acts between native and non-native speakers of a particular language. The best studied interlanguage is that developed by speakers of English as a second language. Other interlanguages that have been investigated include Chinese, German, Hebrew, Japanese, and Spanish (see Huang (2006) for further discussion).

A few recent formal and computational approaches to speech acts and speech act theory are worthy of note. One important theoretical development is the integration of speech acts with intensional logic, resulting in what is called 'illocutionary logic' (Searle and Vanderveken, 1985; Vanderveken, 1994, 2002). Similarly, Merin (1994) has endeavored to produce an algebra of what he calls 'social acts.' Finally, recent formalizations of various aspects of speech act theory in artificial intelligence and computational linguistics can be found in Perrault (1990), Bunt and Black (2000), and Jurafsky (2004) (see also Sadock, 2004).

Language as Action: Performatives vs Constatives

J. L. Austin (1962), in his posthumously published book *How to do things with words* was the first to introduce the idea of speech acts (SA), analyzing the relationships between utterances and performance. His first goal was to point out the limitations of truth conditional semantics, i.e., the (logical positivist) view of language that places truth conditions as central to language understanding. Austin was convinced that we do not just use language to say things (make statements), but also to do things (perform actions). He formalized this opposition in his so-called performative hypothesis (which he would later abandon) by contrasting two types of utterances: constative utterances, or constatives, and performative utterances, or performatives (see **Speech Acts**).

Constatives are essentially like the classical statements. Their function is to describe some event, process, or state of affairs. The proposition that is expressed can be either true or false. Some examples are given in (1). Note that actually, at the time of this writing, at least one of these utterances is false.

- (1) a. I'm driving a green car.
b. I have four children.
c. I am expecting a baby.

By contrast, performatives are utterances that have no truth conditions (see below), but this does not mean that they are meaningless, as illustrated by the examples in (2) (from Truckenbrodt, 2004).

- (2) a. I sentence you to 2 years in prison.
b. I name this ship 'Liberté.'
c. I accept your offer.
d. I promise to pick you up at the airport.
e. I warn you not to come to my house again.
f. I advise you to stop smoking.

Formally, the utterances in (1) and (2) are alike. They are all declarative sentences, in the first person singular, and use the present tense. They do not, however, do the same job. While the utterances in (1) are statements, the utterances in (2) are used to perform an action, i.e., to do something (promising, warning, advising, etc.), rather than to say that something is or is not the case. To be successful, the performative must be issued in a situation that is appropriate, in all respects, for the act in question: if the speaker does not meet the conditions required for its performance, then the utterance will be 'unhappy,' 'void,' or 'infelicitous' (Austin, 1975: 14).

The conditions of 'happiness' of performative utterances (later called felicity conditions, see below) state how and when utterances are valid, in a real situation. A performative can be unhappy in two ways:

- The circumstances and conditions in which the utterance is performed are not appropriate

(incorrect uttering of the formula, the actors involved do not meet the conventional requirements, the speaker is joking, etc.), in which case the act in question is not successfully performed at all, i.e., it is not achieved; or

- The utterance is issued insincerely (such as when I say *I promise* and have no intention of keeping it), in which case the act is achieved but with abuse of the procedure (I have promised but will not follow my promise).

Summing up, performatives are different from constatives in at least two ways (see also Truckenbrodt, 2004). First, performatives are used to do something, they create new facts (other than the fact that someone has said that something is or is not the case). Thus, a judge saying (2a) under the right circumstances in court creates the fact that the hearer is sentenced to 2 years in prison. An authorized person saying (2b) in the right circumstances creates the fact that the ship now has a name. Likewise, by saying (2c) the speaker creates a fact of commitment to accept the offer. By promising, as in (2d), a promise has been made that has consequences. Similarly, in (2e), the listener has been warned; and in (2f), the listener has been given advice. These facts may seem to be relatively similar to the fact created by a statement (*viz.*, that someone has said that something is true). Nevertheless they are different. As Austin clearly indicated, for example, an explicit promise as in (2d) is not, and does not involve, the statement that one is promising. It is an act of a distinctive sort, the very sort named by this particular performative verb (*to promise*). Of course one can promise without doing so explicitly by using the performative verb *promise*, but if one does use it, one is, according to Austin, making explicit what one is doing but not stating that one is doing it.

The second way in which performatives are different from constatives is that performatives cannot be said to be true or false. If the utterances in (2) are performed under the appropriate circumstances, there is no issue of them being true or false. If they are made under the right circumstances, and by the right person, they may be said to be automatically true, in a certain sense. But if they are not made under the appropriate circumstances, they do not become false; rather they become unhappy or void, as shown above. It is clear that this is different from a statement being false. Instead, the statement represents an attempt to perform an act of the relevant kind, but an attempt that does not work out.

What About Grammar?

Performatives normally involve a first person subject (typically *I*) and a performative verb, as in (2) above (where the performative verbs are *promise*, *name*,

etc.). Working with examples of everyday language to show how performances can happen, Austin (1975: 151) claimed five general classes of performative verbs (even though he admits that the distinction between various kinds of utterances is not always clear):

1. Verdictives, which give a finding or verdict by a jury, arbitrator, or umpire (sentencing, pleading, pronouncing, etc.).
2. Exercitives, which are the exercising of a power, right, or influence (appointing, voting, ordering, urging, advising, warning, etc.).
3. Commissives, which commit you to an action, including declarations or announcements of intention (promising, announcing, opening, declaring, etc.).
4. Behabitives, expressing attitudes about social behavior (apologizing, congratulating, commending, condoling, cursing, challenging, etc.).
5. Expositives, which make plain how utterances fit into conversations or arguments (I reply, I argue, I concede, I illustrate, I assume, etc.).

Performatives moreover tend to use the simple present tense and are indicative (*I promise I'll come tomorrow*). This is because they are pronounced for the purpose of acting on a real situation, and thus they usually cannot refer to past events. Nevertheless, performatives are also regularly found in the passive voice, as in (3) (from Austin, 1975: 57).

- (3) You are hereby authorized to pay.
Passengers are warned to cross the track by the bridge only.
Notice is hereby given that trespassers will be prosecuted.

Noteworthy about these examples is that they contain the adverbial *hereby*. The insertion of this adverb is indeed often suggested as a test meant to distinguish performatives from constatives. All utterances in (2) allow the presence of *hereby* (see [4]), while the constatives in (1) do not (see [5]).

- (4) a. I *hereby* sentence you to two years in prison.
b. I *hereby* name this ship 'Liberté.'
c. I *hereby* accept your offer.
d. I *hereby* promise to pick you up at the airport.
e. I *hereby* warn you not to come to my house again.
f. I *hereby* advise you to stop smoking.
- (5) a. # I'm *hereby* driving a green car.
b. # I *hereby* have four children.
c. # I am *hereby* expecting a baby.

This difference between constatives and performatives is found across languages. In French *par la présente* works like English *hereby*, the German

counterpart is *hiermit*, the Dutch one is *bij deze(n)*, the Spanish one is *por la presente*, etc.

As mentioned above, it is not absolutely necessary to actually pronounce the performative verb *to promise* to perform the action of promising. In principle, utterance (6a) will probably have a similar effect on the hearer as does utterance (2d), repeated here as (6b) for convenience.

- (6) a. I'll pick you up at the airport.
b. I promise to pick you up at the airport.

Thus, in some sense, all verbs can be performatives. To account for this, Austin refined his classification: the utterances called performatives above are now called explicit performatives. These are distinguished from primary performatives, in which the performative part is implicit, as in (6a). Austin eventually realized that explicit constatives function in essentially the same way as performatives. After all, a statement can be made by uttering *I assert ...* or *I predict ...*, just as a promise or a request can be made with *I promise ...* or *I request ...*. In addition, the utterances in (7) illustrate that explicit constatives can co-occur with *hereby*, and that they are automatically true, which makes them totally identical to explicit performatives, whereas the corresponding primary performatives to (7) are statements, not actions (see [8]).

- (7) a. I (hereby) tell you that I am not traveling to the U.S. next week.
b. I (hereby) assert that this president is the most stupid one we ever had.
- (8) a. I am not traveling to the U.S. next week.
b. This president is the most stupid one we ever had.

As pointed out by Thomas (1995), Austin's performative hypothesis convincingly documented the fact that people do not use language just to make statements about the world: they also use language to perform actions that affect the world in one way or another. However, the position that **only** performative verbs could be used to perform actions turned out to be untenable. Thomas (1995: 44–46) gives three different reasons for the collapse of Austin's performative hypothesis.

- There is no formal (grammatical) way of distinguishing performative verbs from other sorts of verbs. Like all other verbs, performatives can be plural as well as singular, they can be written and spoken, they do not have to be in the first person, nor is it essential that they be in the active mood.
- The presence of a performative verb does not guarantee that the specified action is performed. One can indeed use the verb *to promise* to actually perform a threat, rather than a promise, as in

I promise things will go wrong for you if you don't go to bed immediately!

- There are ways of doing things with words that do not involve using performative verbs. Indeed, for a great many very common acts such as offering, boasting, expressing an opinion, hinting, insulting, etc., it would be most odd to use a performative verb. In addition, there are also acts for which the language does not even have a performative verb, such as letting the cat out of the bag, putting one's foot in it, pulling someone's leg, etc.

As a consequence, Austin completely abandoned his original distinction between constative and performative utterances; instead, he distinguished between the truth conditions of statement and those of the action it performs. In other words, the proper distinction is that between locutionary and illocutionary acts.

Locution, Illocution, Perlocution

In addition to providing the insight that utterances are used to perform actions, speech act theory assumes that speakers are simultaneously involved in three different speech acts when uttering a sentence:

1. a locutionary act: the act of using words to form sentences, those wordings making sense in a language with correct grammar and pronunciation.
2. an illocutionary act: the intended action by the speaker, the force or intention behind the words, within the framework of certain conventions.
3. a perlocutionary act: the effect that an utterance has on the thoughts, feelings, attitudes, or actions of the hearer.

These acts are not parts, but dimensions of a speech act, which means that they cannot be performed in isolation. Any utterance will always exhibit all of these different dimensions. Thus, in order to have a speech act one needs a meaningful linguistic expression (locution), that is produced, one, with some kind of function or communicative purpose in the speaker's mind, such as making a statement, an offer, an explanation, a threat, etc., (illocution), and two, with some intended effect on the hearer, such as to get the hearer to perform some action, or to have her/him understand a problem, etc., (perlocution). Bach (2003) illustrates this with the example given in (9):

- (9) The bar will be closed in five minutes.

In uttering (9), a bartender would be performing the *locutionary* act of saying that the bar (i.e., the one he is tending) will be closed in 5 minutes (from the time of utterance). In saying this, the bartender is performing the illocutionary act of informing the

patrons of the bar's imminent closing (and perhaps also, and not unimportantly, the act of urging them to order a last drink). Finally, the bartender also intends his utterance to produce further effects, by performing the perlocutionary acts of causing the patrons to believe that the bar is about to close and of actually getting (and not just urging) them to order one last drink. He is performing all these speech acts, at all three levels, just by uttering the above words.

Of these three dimensions, the one most discussed is the illocutionary act (also referred to as the illocutionary force). The term 'speech act' has indeed come to refer exclusively to this kind of act, which thus corresponds most closely to the notion of performative described above, as they can (but need not) be performed by means of a performative formula.

What About Grammar?

Generally speaking, there is a close and predictable connection between locution and illocution of an utterance. That is, all competent (adult) speakers of a language can mostly predict or interpret the intended illocutionary force of an utterance with reasonable accuracy. As pointed out by Thomas (1995: 50), "human beings simply could not operate if they had no idea at all how their interlocutor would react (...)." Most typically, the sentential moods declarative, interrogative, and imperative are used with the functions shown in **Table 1** (based on Truckenbrodt, 2004).

However, this relation between form and function only works in the typical cases (and it remains questionable whether these cases are the most frequent ones). Clearly, we cannot say: a declarative has by definition the function of a statement, or an interrogative has by definition the function of a question (see below). This means that sometimes things can go wrong, mostly because the same locutionary act can have different illocutionary forces. For instance, depending on the context of utterance, (10) – a declarative – could count as a prediction, a promise, or a warning.

(10) I'll be back.

The most obvious way to help the hearer recognize the intended illocutionary force of an utterance is by

using an explicit illocutionary act. Explicit acts contain a so-called IFID or illocutionary force indicating device, i.e., an expression naming the act. In most cases, this is a performative verb that explicitly names the illocutionary act being performed (I *warn* you that, I *predict* that, I *promise* that, etc.). While speakers do not always make their speech acts this explicit, still the context may force them to identify the speech act being performed. This is illustrated in the (constructed) telephone conversation in (11) (from Yule, 1996: 49–50).

- (11) Him: Can I talk to Mary?
 Her: No, she's not here.
 Him: I'm asking you – can I talk to her?
 Her: And I'm telling you – SHE'S NOT HERE!

In this scenario, each speaker describes the illocutionary force of their utterances. Most of the time, however, no performative verbs are mentioned. Yule (1996) mentions some further IFIDs that can draw the attention to the illocutionary force being employed, such as word order, stress, intonation, changes in voice quality, etc.

Of course, to be recognized, the utterance should also be produced under certain (conventional) conditions for it to count as having the intended illocutionary force; that is, it should meet a number of felicity conditions, a notion that was developed by Searle (1969), building on Austin's original work. In addition to the general conditions on the participants (such as that they understand the language being used and that they are not play-acting or uttering nonsense), Searle distinguishes preparatory, propositional, sincerity, and essential conditions, differing as to the function of the speech act at hand. Example (12) illustrates the conditions for the act of *promising* (Searle, 1969: 62ff; as cited in Saeed, 2003: 229):

- (12) Conditions for promising
 [where S = Speaker, H = Hearer, A = the future action, P = the proposition expressed in the speech act, *e* = the linguistic expression]
 a. Preparatory 1: H would prefer S's doing A to his not doing A and S believes H would prefer S's doing A to not doing A.
 b. Preparatory 2: It is not obvious to both S and H that S will do A in the normal course of events.
 c. Propositional: In expressing that P, S predicates a future act of S.
 d. Sincerity: S intends to do A.
 e. Essential: the utterance *e* counts as an undertaking to do A.

Thus, the preparatory conditions for a promise should guarantee that when I promise to do something, the event will have a beneficial effect on the

Table 1 Relationship between form and function of speech acts

Syntactic form	Illocutionary act	Illocutionary force
Declarative	Statement	Speaker commits to content
Interrogative	Question	Request for information
Imperative	Command	Attempt to get listener to do something

hearer, and second, it will not happen by itself. So, telling one's spouse *I'll be home at six* when leaving for work might not be considered a typical promise, unless I usually come home at seven or eight and my spouse would like me to come home earlier. The propositional condition reflects the fact that the content of the utterance has to concern a future event – I cannot promise something that already has happened – and that the future event will be an act of the speaker – I cannot promise my family that our neighbor will do the dishes tonight. Related to these conditions is the sincerity condition: when I promise to do something, I really must intend to carry out the future action – I cannot genuinely promise that I will be home at six if I already know that I have a meeting starting at six! Finally, the essential condition covers the fact that by uttering my promise, I commit myself to the obligation of carrying out the future action.

According to Searle, the conditions related to the speech act of promising are of general applicability and thus it should be possible to establish rules of this type for every speech act. Searle does so for some eight additional speech acts: requesting, asserting, questioning, thanking, advising, warning, greeting, and congratulating. Thomas (1995: 95ff), however, criticizes Searle's endeavor and raises four interrelated sets of problems with respect to these rules:

- It is not always possible to distinguish fully between one speech act and another (partly because the conditions specified by Searle only tend to cover the central or most typical usage of a speech act verb).
- If we attempt to plug all the gaps in Searle's rules, we end up with a hopelessly complex collection of *ad hoc* conditions.
- The conditions specified by Searle may exclude perfectly normal instances of speech act, while they would permit anomalous uses.
- The same speech act verb may cover a range of slightly different phenomena and some speech acts do indeed overlap; Searle's rules do no account for this.

Categorizing Speech Acts

Any language has probably several hundred verbs that can be used to describe a kind of action that can be performed with an explicit or an implicit speech act. Is there a plausible way of grouping all these different speech acts into categories? In contrast to Austin's (1962: 109ff) first, very tentative classification, based on actual performative verbs

(a classification which he did not consider definitive), Searle's (1976) categorization of speech acts into five types, each with their general function, has become a classic, and is still often referred to today. Its main improvement with respect to Austin's is probably that it clearly separates the notion of speech act from that of speech act verb. In other words, "the existence or nonexistence of [a speech act verb (or performative verb)] cannot be a criterion for the existence or nonexistence of a particular speech act" (Mey, 2001: 117) (see **Speech Acts, Classification and Definition**).

1. Representatives commit the speaker to something's being the case, to the truth of the expressed proposition, typically statements, assertions, conclusions, descriptions, etc., such as *The earth is flat; It's cold here; Chomsky didn't like butterflies*.
2. Directives are attempts by the speaker to get the hearer to do something. They express what the speaker wants; typical representatives are commands, orders, requests, suggestions, etc., such as *I warn you to stay away from my house!; Mum, can I have a cookie, two please?*
3. Commissives commit the speaker to some future course of action. They express what the speaker intends: typically, promises, threats, refusals, offerings, etc., such as *I promise that I'll be home at six; I'll be back; I will not marry you*.
4. Expressives are used to express the psychological state of the speaker. They state what the speaker feels and can be statements of joy, pain, sorrow etc., but also expressions of thanking, apologizing, welcoming, congratulating, etc., such as *I congratulate you on winning the race; I'm really sorry; YESSS!*
5. Declarations effect immediate changes in the institutional state of affairs, i.e., they change the world via the utterance. The speaker has to have a special institutional role, in a specific context, in order to be able to perform a declaration appropriately; typical examples include excommunicating, declaring war, marrying, firing from employment, nominating, etc.

Searle uses a mix of criteria to establish these different types; these include the act's illocutionary point, its fit with the world, the psychological state of the speaker, and the content of the act (cf. Saeed, 2001: 228–229; Mey, 2001: 119–126). The illocutionary point is the purpose or aim of the act; it corresponds most closely to the definition of the speech act types given above. The fit concerns the direction of the relationship between language and the world: should the words conform to the world (representatives, expressives) or is it the world that should conform to the words (directives,

commissives), or be changed by the words (declaratives)? The psychological state relates to the speaker's state of mind or attitude toward events: e.g., does the speaker believe what is uttered in the speech act, or not? Finally, the content is directly related to the propositional felicity condition described above.

What About Grammar?

An alternative way of classifying speech acts is to take their structure as a point of departure. In their cross-linguistic analysis of speech acts, Sadock and Zwicky (1985: 160) note "that most languages are similar in presenting three basic sentence types with similar functions and often strikingly similar forms." These three basic sentence types are the declarative, the interrogative, and the imperative. Roughly, they can be described as follows: The declarative is used for making announcements or declarations, stating conclusions, making claims, telling stories, and so on. The interrogative is used to gain information; it asks for a verbal response from the addressee. The imperative is used for making requests, giving orders or advice, making suggestions, and the like; its use is meant to influence the course of (future) events. While there are many differences in detail between individual languages, there seems to be "an easily recognized relationship between the three structural forms (declarative, interrogative, imperative) and the three general communicative functions (statement, question, command/request)" (Yule, 1996: 54), as illustrated in (13):

- (13) a. She eats an apple. declarative/statement
- b. Does she eat an apple? interrogative/question
- c. Give me her apple! imperative/command

Whenever there is such a direct relationship between the sentence type and its communicative function, we are faced with a direct speech act. Whenever the relationship between structure and function is indirect, we are dealing with an indirect speech act. Thus, an interrogative used to ask a question is a direct speech act (as in 13b), but an interrogative used to inquire about a capability (*could*, *can*) or willingness (*would*) in order to elicit information (14a) or to make a request (14b, 14c) represents an indirect speech act (*see Speech Acts, Literal and Nonliteral*).

- (14) a. Could you tell me whether she's eating an apple?
- b. Can you give me the salt, please?
- c. Would you give me your suitcase, Madam?

The examples in (14) actually display "a typical pattern in English whereby asking a question about the

hearer's assumed ability (*Can you?*, *Could you?*) or future likelihood with regard to doing something (*Will you?*, *Would you?*) normally counts as a request to actually do that something" (Yule, 1996: 56). The same goes for other languages (such as Dutch, French, German, Spanish, and so on) where similar patterns are displayed.

From a more general point of view, indirectness is a universal phenomenon (Thomas, 1995: 119). It can be used to make one's language more or less interesting; to increase the force of one's message, to reach competing goals; and to be more polite or to save one's face (see Thomas, 1995: 143–146) (*see Face*). Indirect speech acts, in particular, are generally associated with greater politeness than are direct speech acts. However, it is not possible to assess politeness out of context. The linguistic form, as well as the context of utterance, and the relationship between speaker and hearer, all play a role in rendering a speech act more or less polite (or impolite; see Thomas, 1995: 155–157) (*see also Politeness; Pragmatics: Overview; Pragmatic Acts*).

Speech Acts, Classification and Definition

A Capone, Barcellona, Italy

© 2006 Elsevier Ltd. All rights reserved.

To speak a language is to express thoughts in the form of linguistic utterances that employ words and follow combinatorial rules. When a person A speaks communicatively, she transmits a thought to a hearer H with a certain **official aim** and possibly with other consequential effects. By an utterance, a speaker can inform the hearer of a certain situation, express an inner state of mind (emotions or feelings), or modify the behavior of the recipient. In all cases, a certain thought is expressed by the vocalization of an utterance. A speech act, though, is not merely the expression of a thought. It is the vocalization of a certain representation of the world (external or internal) aimed at making official the display of an intention to change a state of things and at changing things by the public display of that intention. A speech act is a **public utterance**; it cannot be a silent thought, and its effects are obtained in virtue of its being a public thought. I hope that this suffices to settle the question of whether the communicative or the representational

view of language should have priority. My stance is that we have to start with the basic function of language, which is that of expressing or articulating thoughts, before we can move on to the public function of language, which is to express communicative intentions to obtain a number of effects on other people and on society. Thus, this view reconciles opposite stances to language.

We have to distinguish 'locutionary,' 'illocutionary,' and 'perlocutionary' acts. A locutionary act is the vocalization of a sentence endowed with a certain meaning. For example, an actor on the stage vocalizes a locutionary act, because the meaning that the utterance has, is not interpreted as being a display of the speaker's intention. An illocutionary act is an utterance proffered with the intention to change the context, updating it with a certain public intention to do things or modify the hearer's cognitive state. A perlocutionary act is an utterance that achieves the speaker's intention, not directly through the expression of that intention, but as a **consequence** of the display of a speaker's intention to do something. For example, an anonymous letter to the police may have as its point the (perlocutionary)

intention to jam the police activities and divert the course of justice.

In this article, I contend that there is a general algorithm, mapping a sentence type to a literal speech act; in other words, there are conventions of language use associating certain forms with certain speech acts. This is certainly the case of 'performatives' (e.g., *I promise to come tomorrow*; *You are fired*; etc.), forms which **unambiguously** express a certain illocutionary intention and the utterance of which counts as carrying out certain social actions. When a performative formula is used by a person having certain socially recognized characteristics (status, power, etc.) in an appropriate context, then a certain social action is carried out in virtue of the speaker having proffered the formula in that context. The case of utterances that do not wear their illocutionary potential on their sleeves is less certain, in that the context can shape the final illocutionary force of the utterance. However, it is useful, in my opinion, to think of the language system as providing default conventions whereby proffering a certain utterance, in virtue of a convention of use, counts as performing a certain speech act, unless the context intervenes to enrich the force of the utterance further. The basic objections to this view (counterexamples to basic correlations) can be answered by having some weak conventions of language use map utterances to very generic illocutionary forces that can be enriched further by the specification of the full context in which the utterance is situated.

It is useful here to abandon the view that there are sentences whose illocutionary potentials can be studied in isolation, and to replace it with one in which, although the very basic contribution of linguistic semantics is not dismissed altogether, one specifically studies speech acts in actual interaction, embedding them in large portions of context having the function of incrementing the illocutionary potential of a certain sentence. We will thus move on to a higher unit of linguistic analysis: the 'pragmeme.' (Mey, 2002: 222) We may provisionally define the pragmeme in this way:

Take an utterance *U* of a sentence *S* in a cotext *S'*, *S''*, *S'''*, *S_n*, or a sequence *S_q* of utterances, uttered in a situation of utterance *C*, in which the language users know that the sequential placement of *U* or *S_q* contributes to the illocutionary force in virtue of a rule of language use pertaining to that limited area of use. Then the utterance of *U* or *S_q* in the cotext *S'*, *S''*, *S'''*, *S_n* and in the situation *C* will transform *U* or *S_q* into a pragmeme *Pr* having a certain illocutionary force *IF*, partially determined by the semantic import of the sentence in question, by referential pragmatic enrichments and explicatures, and by the final transformation due to the contextual and cotextual elements of the sequence *S'*, *S''*, *S'''*, *S_n*, in *C*.

As can be noted, in the definition above we have avoided the ordinary assumption that there is a one-to-one mapping between an utterance (consisting of a single sentence) and an illocutionary act, preferring the general case in which a sequence of sentences (or utterances) counts as the vocalization of a single speech act (see **Pragmatic Acts**).

Before moving on to the important issue of speech act classification, it is important to try to settle the perennial question of whether speech acts can or cannot be reduced to truth-conditional meaning. In fact, speech act theory, as worked out by Austin (1962), seems *prima facie* to challenge the view that semantics can be reduced to truth-conditional meaning, because at least a number of speech acts (e.g., promises, directives, requests, etc.) do not represent thoughts or facts, but are instructions to change the world in a manner specified by the speech act at hand. In fact, Gazdar (1979) and Levinson (1983) persuasively write that speech acts are best described as transformations from a certain context to a new one (see Austin, John L.; **Speech Acts**). Of course, there are advantages to glean from this perspective, but it has not been demonstrated, according to a number of authoritative scholars, that a speech act does not express a thought, the intention on the part of the speaker to carry out a certain action. Surely, a person who asks a question expresses the wish to know a certain answer; a person who proffers a directive vocalizes the wish that the world be changed in such-and-such a way; a person who utters a promise expresses the thought that he or she will act in a certain manner in the future that will create some advantages for the hearer. I believe that all this is indisputable, and I am not sure how it can be reconciled with the drastic view proposed by Austin and then followed by Levinson (1983) that speech acts cannot be reduced to truth-conditional meaning. After all, having a thought amounts to creating a state of affairs (albeit enveloped in the mind) that surely can be expressed by truth-conditional semantics, as this is specifically intended to describe states of affairs, either in the world or in the mind (and states of affairs in the mind are in the world, as a consequence of the fact that the mind is in the world).

One way to reduce speech acts to truth-conditional meaning is through partitions (Higginbotham, 1995). Consider a question such as 'Is John at home?' Because the question just admits two possible replies (Yes, he is; No, he is not), the speech act is associated with the partition [He is at home/he is not at home], which expresses the basic truth-conditional import of the question. A crucial observation to make, following Schiffer (2003), is that while we can happily say that the question is associated with this partition, it is

not clear (and it is possibly wrong to think) that we are entitled to say that the question means what the partition means. At least, this is not the way we would ordinarily speak. More complicated are questions such as 'Which boy did you see in town?' where the partition consists of all the reply options related to the domain of the boys present in town (for all those boys, we have to consider the reply option [I saw x/ I did not see x]).

I tentatively propose another way to solve the problem of speech acts' reduction to truth-conditional meaning, by recourse to modal notions. Consider the following sentence:

Go and buy some bread.

This sentence can be represented in the following way:

In a world *w* that is maximally similar to the actual world, such that the obligations imposed by the speaker on the hearer in virtue of linguistic conventions and of social conventions (for example, the institutional role played by the speaker or the kind of obligations under which the hearer has put himself are fulfilled, the hearer (or the recipient of the speech act in question) buys some bread.

Of course, this is no more than a sketch of a possible solution, but I am persuaded that it goes some way toward remedying the dichotomy between assertions and nonassertive speech acts, while allowing us to retain a more commonplace notion of meaning than that advocated by Higginbotham and his followers, using the plain and salutary intuitions by Schiffer.

It is now time to move on to a basic classification of speech acts. Let us start with 'assertions.' A speaker *S* asserts *P*: (a) if he or she believes he or she knows that *P* is true (or he or she feels justified in believing that *P* is true), and (b) if he or she further believes that the proffering of the assertion will effect a substantial change in hearer *H*'s information state. The presupposition of an assertion *P* (which is not to be treated as a 'reminder') is that (a) the hearer does not know *P*, and (b) either he or she is interested in knowing *P*, or even in the case when he or she would prefer not to know *P*, the speaker has a moral duty to inform *H* of *P*. Part of the dynamics of asserting *P* is that the speaker believes that *H* can use the information contained in *P* to make plans for successful action. Although the assertion *P* amounts to an implicit claim on the part of the speaker that he or she knows that *P* is true, it is not necessary for the speaker to actually know that *P* is actually true in order to make such an assertion. What is indispensable is that the speaker has (subjective) reasons to believe that he

or she has good grounds for asserting *P*. Neither is it necessary that the speaker should stick to his or her asserted proposition after it has been demonstrated through an evidential procedure that it is wrong. He or she can change his or her mind about *P* and retract the assertion, although by doing so he or she must give reasons for entertaining a different thought. 'Expressives' are to be treated separately from assertions because they are disclosures of the reality of the mind and of the heart, and are not verifiable except by reference to the consonance of a speaker's behavior with such disclosures. 'Directives' express the speaker's wish that the hearer do such-and-such a thing and are uttered with the presumption that the hearer is under some obligation to carry out the action in question (status and roles within an office or an institution determine the right to utter the directive in question). 'Requests' also express the speaker's wish that the hearer behave in such-and-such a way. Requests are not licensed by the formal rights acquired by being part of an institution, but by the obligations contracted by the hearer throughout previous interaction. 'Promises' are revelations of future behavior on the part of the speaker from which the hearer will glean some advantages. Promises concern actions that have been presumably solicited by the hearer (or by someone close to the hearer) (see *Speech Acts and Grammar*).

Speech Acts, Literal and Nonliteral

A Capone, Barcellona, Italy

© 2006 Elsevier Ltd. All rights reserved.

There has been a long and fierce battle between the communication-oriented philosophers of language and the formal linguistics theoreticians regarding the priority of language as a means of expressing thought over a vision of language as an instrument of communication. The philosopher Dummett, in a conciliatory tone, has attempted to demonstrate that both positions – in their radical assumption that the other view is misguided – are wrong and that the two ideas about language are compatible. According to Dummett (2003), the idea that language is used to communicate presupposes the view that language is a way of expressing (or articulating) thoughts. The idea that language is merely an instrument of the expression of thought, in his view, collapses when we consider solipsistic uses of speech acts (a person's writing a reminder to himself and hanging it on a kitchen wall, or a person's trying to find an answer to his own question). Such solipsistic uses still presuppose a derived idea of communication.

In this article, we grant that language is primarily an instrument of thought (enabling the articulation of thought); however, we also think that language is an instrument of social action. An utterance *U* expressing the thought *X* performs an action *A* if, by the expression of *X*, a certain configuration of elements (roles, rights, duties) is changed from state *S* to state *S'* (*A*) (*S'* being a function of *A*) not as a result of the indirect consequences of the thought *X* but as a result of the socially recognized effects of vocalizing it, brought about by the recognition of the thought *X* and of the official position that the speaker of *U* has taken by publicly vocalizing such a thought. A speech act is not brought into effect unless a thought *X* expressed by an utterance associated with *X* is recognized as having been in the mind as well as in the mouth of a speaker. Suppose I have the ability to decipher Sally's intentions by reading her mind, and her thoughts contain a sentence *S* conventionally associated with a speech act *A*; nevertheless, the silent utterance (her thought) has no social effect, as its vocalization has not been heard in public.

Speech acts have their effects not only because certain persons have appropriate thoughts, but mainly because these thoughts have been publicly expressed by means of utterances, that are socially noticeable events, bound to have certain conventional social consequences. A speech act *A* is normally brought into effect by means of a device that

indicates illocutionary force, essentially some linguistic means conventionally adopted to vocalize a certain thought that, once it is vocalized in public, becomes associated with an action *A*. There has been a long controversy as to whether moods are in some ways associated with certain illocutionary forces, resulting in the abandoning of the respectable and reasonable orthodoxy that declarative sentences, interrogative sentences, and imperatives are normally associated with certain actions, such as expressing thoughts, asking questions, and modifying other people's behavior (Levinson, 1983). Very luckily, a number of linguists, including Geis (1995) and Capone (2003), have returned to the orthodoxy. It would be unreasonable to suppose that distinctions of mood have no semantic counterparts, as that would require admitting the vacuity of certain fundamental linguistic distinctions. If there are linguistic distinctions, these must have semantic work to do, and it is reasonable to expect them to be related to illocutionary forces, at least of basic types (very generically specified). This article follows Geis in distinguishing between the *literal speech act* performed in virtue of uttering a sentence having a certain mood and the *full, context-dependent cognate speech act*. The full, context-dependent speech act, in this author's opinion, is still a function of the corresponding literal speech act, context playing a role in further determining the illocutionary force of the utterance. The role pragmatics plays in fully determining the content of a speech act in context is to add features of meaning to the underdetermined speech act; thus, it is always possible to return from the contextualized speech act to the literal speech act by subtracting the features added by the context. Contextual transformations, in this author's view, are **conservative**, and the basic meaning structure can be identified both at the beginning and at the end of the transformation.

The full import of a speech act is determined by the interaction between the literal speech act and the context of use. As Mey says:

Speech acts, in order to be effective, have to be situated. That is to say, they both rely on, and actively create, the situation in which they are realized. Thus, a situated speech act comes close to what has been called a speech event in ethnographic and anthropological studies (Bauman and Sherzer, 1974): speech as centered on an institutionalized social activity of a certain kind, such as teaching, visiting a doctor's office, participating in a tea-ceremony, and so on. In all such activities, speech is, in a way, prescribed: only certain utterances can be expected and will thus be acceptable; conversely, the participants in the situation, by their acceptance of their own and others' utterances, establish and reaffirm

the social situation in which the utterances are uttered and in which they find themselves as utterers (Mey, 2001: 219).

I will call fully contextualized speech acts ‘pragmemes,’ on the basis of terminology by Mey (2002). A pragmeme is a speech act – an utterance associated with a goal (and an intention to bring about such and such effects), which is to modify a situation and change the roles of the participants within that situation or to keep the roles the same while bringing about other types of effects, such as exchanging or assessing information, or engaging in an interactional episode whose significance lies in the production of social gratification or, otherwise, social bonds.

Such a speech act is *situated*, which means that the specific form the utterance takes, interacts with features of the cotext and with the situation of utterance (see **Context, Communicative**), including the rules entailed by such a situation, that jointly determine (or contribute to determining) the global significance of the act in question. Given a sequence of utterances – literally interpretable as having a certain meaning and a certain goal – features of the situation of utterance, in the form of pragmatic reasonings based on the Gricean maxims (see **Maxims and Flouting**), will complete or expand the minimal proposition presented by the utterance, anchoring it to the discourse in question; other features of the context of utterance, in the form of defeasible or otherwise noncancellable aspects of meaning, will transform the literal signification of the utterance into a situational signification, removing ambiguities and imposing the stamp of the situation on the utterance, making certain rules of interpretation relevant to it and constituting a set of constraints that strictly enforce certain readings by discarding or eliminating other, irrelevant interpretation options.

A pragmeme is a situated speech act (Mey, 2001: 94) in which both the rules of the language and the rules of society intervene in determining meaning, intended as a socially recognized object sensitive to social expectations about the situation in which the utterance to be interpreted is embedded. A pragmeme always requires three types of embedding: the embedding of an utterance in a context of use, with an aim to determine the referential anchors that complete the signification of the utterance; the embedding in rules that systematically transform whatever gets said in a context into whatever is meant there; the embedding in the cotext, whose features are transferred onto the utterance by eliminating semantic or otherwise interpretable ambiguities and enriching further its (range of) interpretations, by making them more specific.

This article now discusses another example of language use in which the macro aspects of the situation contribute to transforming the illocutionary potential of an utterance. Capone (2005) discusses the utterance ‘I saw you’ in the context of a story by the Italian novelist Italo Calvino. Within the theoretical apparatus of Gricean pragmatics, the author argues that the standard illocutionary force of the utterance (both in the Italian and in the English version) is that of an accusation. There are, however, special contexts in which the utterance acquires particular illocutionary forces.

Let’s look at the game played by children, usually under 10 years old, called hide-and-seek. In this game, one of the children has to count up to (say) 20, facing a wall or a tree and with his or her eyes shut. Upon finishing the count, he or she must then look for the other children. When he or she spots one of them, he or she has to call out ‘I saw you’ and then runs back to the place where the game started (wall or tree). The child who arrives there first wins. Now, what is the import of ‘I saw you’ in this situation? Do we proceed from literal meaning until we arrive at the socially situated meaning? Do the literal meaning and the socially situated meaning diverge? It is not altogether clear to me that we are faced here with a crucial divergence. But what is the socially situated meaning of ‘I saw you’? We can assume that in the situation of the game, from an informational point of view ‘I saw you’ is totally purposeless, as visual contact ensures in the standard case that it is obvious to both the speaker and the addressee that the latter has been spotted (of course, there may be situations in which a physical obstacle prevents this mutual vision). In the game, however, the purpose associated with the utterance is to start a sequence in which the children start running at the same time to the place where the game started. In its performative aspects, the utterance roughly amounts to ‘Let’s start running.’ The socially embedded meaning is not at odds with the literal meaning – after all, the assertion ‘I saw you’ provides the reason that the running sequence is initiated.

Another situation in which it is possible to observe utterances such as ‘I saw you’ is the classroom. The teacher notices that Michelangelo (his favorite student) whispers the answer to a question to his desk mate. The teacher says ‘I saw you.’ This is not just an utterance of blaming but an order to Michelangelo to stop doing what he has been doing. How can this speech act be transformed into the pragmeme ‘Stop prompting’? It is the social situation, the rules and expectations about students’ obligations and teachers’ tasks, that promote the *inhibitive interpretation* of ‘I saw you.’ In this context, it is out

of the question that the utterance could count as a compliment – such an interpretation simply cannot occur. In fact, even though the teacher thinks highly of Michelangelo and also admires him for helping his fellow students and even though Michelangelo knows that the teacher has this positive opinion about him, it is unlikely that he will choose a tortuous path of individual interpretation and proceed from considerations about his teacher's high esteem for him to the interpretation that the speech act counts as a compliment. Michelangelo will almost certainly prefer to follow the social path of interpretation rather than construct his own individual path. Thus, he is able to work out that in fact the teacher, despite his high opinion of him, wants Michelangelo to stop prompting answers to his desk mate. This example nicely instantiates the view that the context is the total social setting in which the speech event takes place, the meaning of an utterance being determined by its place in an interactional sequence. It also provides support for Mey's view that users and their language are at the core of all things pragmatic, the world of users being the very condition for doing pragmatics (Mey, 2001: 29).

Speech and Language Community

J T Irvine, University of Michigan, Ann Arbor, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

'Language community' and 'speech community' are constructs developed by scholars of language to refer to a social aggregate within which language is used. Over a century or more of discussion, scholars have differed as to whether the two terms referred to the same type of social formation or two different types. They have also differed as to whether the 'community' is to be understood as an empirically describable object in the world, or as an abstraction or idealization; whether to focus on speakers' knowledge or on their practice – or some combination; whether the aggregate should be considered from the perspective of its homogeneity or its internal diversity; and, most recently, whether the aggregate can be understood as a social whole – a bounded social universe – or whether it can only be understood as part of some larger field of social (and linguistic) relationships. Within these

debates lurk different ontologies of language, society, and their relationship.

Briefly put, then, the problem of defining and identifying the speech community (and/or related terms) is both a theoretical and a methodological problem. The problem is theoretical because it concerns the locus and nature of the forces that shape language(s). What kinds of social relationship or grouping are implicated in what kinds of linguistic system, subsystem, or practice – and vice versa? Do the specifics of social organization matter, or is society no more than a prerequisite and general constraint on what really counts, a neuropsychology of language? The problem is methodological because it concerns where to locate and focus one's research. What is the arena within which to investigate how language is structured? Where should one look, to see how language takes form as social action?

Large though these questions loom in linguistic anthropology, outside this field they are not always seen as problematic. To some commentators it has

seemed obvious that the ‘speech community’ must be an ethnic group that ‘has’ a single common language. This view is associated with the romantic nationalism of the late-18th-century scholar Johann Gottfried Herder, who maintained that a language is the natural hallmark, and the most precious possession, of a people (*Volk*) or nation, reflecting its special spirit and identity. To Herder’s heirs, scholarly and lay, it has seemed natural to suppose that language itself creates – or automatically reflects – community: that there is always some aggregate of people who could be said to ‘share’ a language and who must, by virtue of that fact alone, share a cultural tradition, feel that they ‘belong’ together, and participate jointly in a social formation of some specifiable type – a people (or ethnic group, or nationality). In contrast, many linguistic anthropologists and sociolinguists problematize these connections, resisting the assumption that there is any ‘natural’ relationship between language and community that maps linguistic facts onto social groupings in some universal way. In arguments that have been foundational to our discipline, Franz Boas maintained that language, race, and culture are independent classifications of humankind, and that the distribution of particular linguistic forms does not necessarily predict the distribution of other social and historical facts. Since Boas’s time the issues under debate have become more subtle, but the central theme remains. How languages and linguistic varieties map onto people, activities, and social relations – and how the social constructs may depend on linguistic practice – are the central problems we must address, along with their constituent terms such as ‘community of speakers.’

This article first traces two threads in the history of 20th-century scholarly writings on ‘speech community,’ up to approximately the 1970s. During this period scholarly debate turned on the relationship between individual and society, and on whether to focus attention on what members of a community have in common or on how they differ. I then turn to some more recent discussions and issues, such as the notion of ‘communities of practice,’ language’s relation to social networks, distinctions between ‘language community’ and ‘speech community,’ and debates about the relevance of conflict-based (as opposed to consensus-based) social theories. Finally, I consider whether ‘communities’ can be conceived as wholes or only as parts.

The Homogeneous Speech Community

Let us begin with Ferdinand de Saussure’s ‘mass of speakers’ (*masse parlante*, rendered as ‘community of speakers’ in the widely distributed Baskin

translation of the 1916 *Course in general linguistics* [1966: 77, 78]). The *masse parlante* is the social collectivity that is necessary for language (*langue*) to exist in the real world. This collectivity is the foundation of the ‘social fact,’ the social conventions that establish linguistic signs as vehicles for semiosis. In emphasizing the social nature of language, and the importance of the ‘social fact’ for linguistic theory, Saussure moved away from the individualistic focus of some prominent earlier linguists such as the Neogrammarian Hermann Paul. For Saussure, language as a structured system is collective rather than individual, and because it is collective it is not subject to personal will or the vagaries of individual action. (The history of intellectual links between Saussure, Paul, and other scholars, particularly William Dwight Whitney, is actually more complex but need not concern us here.)

As a collectivity, Saussure’s ‘mass of speakers’ is neither structured nor internally differentiated, and it has no social properties that would lead to differentiation in its participants’ language (*langue*, the representation of linguistic structure). Instead, the collective consciousness exerts pressure on individuals to conform. All representations of language in individual brains are essentially alike, so that a language is like a book whose (virtually) identical copies are deposited in the minds of its speakers. According to the *Course* (Saussure, 1966: 13–14), “[language is] a grammatical system that has a potential existence in each brain, or more specifically, in the brains of a group of individuals. For language is not complete in any speaker; it exists perfectly only within a collectivity.” As the locus of a synchronic collective consciousness, imagined as if extracted from time and action, the ‘social mass’ can only be an abstraction, a virtual community rather than a real one. (Later in the *Course*, Saussure suggests (1966: 223) that the ‘linguistic community’ is generally an ethnic unity. This passage stands quite apart from his discussion of linguistic structure, however.)

Readers today may find that Saussure’s discussion of linguistic systematicity as a matter of mental representations in an abstract, undifferentiated virtual community has much in common with a well-known statement in Chomsky’s *Aspects of the theory of syntax* (1965: 3): “Linguistic theory is concerned primarily with an ideal speaker-listener in a completely homogeneous speech community, who knows its language perfectly...” Like the *masse parlante*, Chomsky’s speech community is an abstraction, not a misperception of an empirical world in which human communities are not perfectly homogeneous. In this view the speech community is little more than a precondition for language, whose locus – and here

Chomsky departs from Saussure – is not in the collectivity but in the ‘mind/brain’ of the individual speaker. So strong is this emphasis on the biological individual, and so downplayed is the speech community, that linguistics is to be conceived as a branch of cognitive psychology.

In contrast to these views of the speech community as an idealization, Leonard Bloomfield’s classic definition (in *Language*, 1933: 29) places the speech community in an empirical world of economic practicality that makes it homogeneous: “A group of people who use the same system of speech-signals is a **speech community**. Obviously, the value of language depends on people’s using it in the same way” [emphasis original]. The value, that is, for a social division of labor where producers with different skills rely on a common code to coordinate the exchange of their products – or so Bloomfield supposed. Notice that this community is envisioned as socially and economically diverse, but uniform in (monolingual) language. Bloomfield’s statement is about society as well as about language, and it makes an empirical claim.

How would this linguistic conformity come about? People who interact frequently will tend to speak alike, Bloomfield believed, because language acquisition is based on imitation and behavioral conditioning. Arising out of the density of communication, which has made participants speak alike, a speech community would be distinguished from its neighbors by breaks in the frequency or intensity of interaction. (In practice, Bloomfield seems usually to have identified the speech community with a tribe or ethnic group – though not, incidentally, with a culture-bearing group, which he suggested was broader.) Within the community there can be ‘lines of weakness,’ slight differences in the frequency of interaction, corresponding to subgroups with slightly different forms of speech. As an example, Bloomfield cited Sapir’s work on male and female speech in Yana. But although he mentioned that the differences between male and female speech in Yana are systematic – a point Sapir had stressed – Bloomfield did not discuss how ‘lines of weakness’ might give rise to differences that were systematic or conventional, rather than random. To propose that differentiation might be conventional would require the linguist to distinguish between the knowledge of linguistic forms and their use in acts of speaking, a distinction Bloomfield’s behaviorist psychology did not easily support.

Anthropologists and linguists have long since discarded Bloomfield’s behaviorist psychology of language. More durable, however, has been his notion that the speech community – the social site for linguistic description – is defined by interaction

frequency. In his early works, John Gumperz identified the ‘speech community’ (or ‘linguistic community’ – in the early 1960s the terms were interchangeable) with some large social unit having a definite boundary around the outside and dense, frequent interaction inside. Unlike Bloomfield’s, however, Gumperz’s speech community could be multilingual. Its presumably dense interaction did not automatically produce homogeneity. So, in a study of a north Indian village, Gumperz (1958) suggested that Bloomfield’s concept needed to be refined so as to distinguish between different kinds of communicative interaction: those that lead to behavioral convergence and those that do not. Despite regular patterns of interaction, the residents of this village did not all speak alike, and the study dealt with the social setting of these linguistic differences.

Similar lessons can be drawn from his work on convergence and creolization (Gumperz and Wilson, 1971), a study of language repertoires in a Maharashtra village whose population included speakers of Kannada, Telugu, Urdu, and Marathi. As a result of long-term proximity, the local varieties of these languages had changed, the authors concluded, in ways that made them more like each other. While the paper is justly known for this argument about grammatical convergence – even utterly unrelated languages may converge in several areas of linguistic structure if their speakers happen to live together for long enough – the convergence can only be described because other aspects of language have remained distinct. In fact, the villagers considered it important to maintain the linguistic distinctness of population subgroups in their multilingual community, and to differentiate between contexts of language use.

The Speech Community as the Organization of Diversity

As Gumperz’s work illustrates, a new focus on linguistic diversity within communities began to emerge in the 1960s in studies of language contact, dialectology, and change. Led by Gumperz, Dell Hymes, Uriel Weinreich, and William Labov, the new work attacked the identification of structuredness with homogeneity (Weinreich *et al.*, 1968: 101). The speech community was now redefined as “a field of action where the distribution of linguistic variants is a reflection of social facts” (Gumperz, 1968: 383). Structure in the speech community rested on the organization of diversity, not merely on the replication of uniformity; its linguistic variation was not just random (Hymes, 1974: 75). The perspective recalls Durkheim’s discussions of organic solidarity, where it is precisely people’s complementary differences that bind them

together, as opposed to mechanical solidarity, where social cohesion rests only on similarity. Thus multilingualism is not chaos, nor is it necessarily a transient or abnormal condition. Instead, it can represent an orderly social consensus.

This vision of speech community places multilingualism, multidialectalism, and communicative repertoires on center stage for observation and analysis, not on the periphery. The repertoire and its deployment in communicative practice are now seen as the crucial place where the relationship between language and social organization lies. Here we might observe how ways of speaking are linked with, and constitute, social groupings and identities, and how ways of speaking are situated in social activities. 'Community,' in the sense of sharing and commonality, lies in the interpretation, not the production, of behavioral forms (including speaking). What is shared is knowledge of how the differences in ways of speaking are organized.

As one of many examples, Hymes pointed to Paraguayan multilinguals who switch between Spanish and Guaraní according to the intimacy or distance of the communicative context. Gumperz (1964), meanwhile, compared the repertoires of two communities, one in India and one in Norway; the two communities' quite different social structures were reflected in the different ways their linguistic repertoires were organized. In each community, members did not equally command all varieties, yet they understood when and where a code might be used – what its social implications were. Elsewhere, the Vaupés region of the northwest Amazon basin offers a particularly compelling example of the organization of linguistic diversity, since the social organization of the region has traditionally depended on a principle of linguistic exogamy: language is a badge of membership in one's patrilineal descent group, within which one may not marry. The marriage relationships that connected these groups and organized them in communities had to be contracted with persons whose linguistic 'badges' differed (see Jackson, 1974). Residential communities necessarily included spouses having different linguistic affiliations, and individuals were highly multilingual.

Notice, however, that if linguistic diversity does not prevent the formation of community in a social sense, then – by the same token – using the same language does not automatically create it. Illustrating this point, Gumperz (1979) described the communicative difficulties faced by a South Asian immigrant and a British interviewer. Despite the fact that their English was grammatically quite similar, the two interlocutors never succeeded in interpreting one another's responses, or in establishing a common

understanding of the interview's purpose. As the example showed, using the same language (in the sense of 'denotational code') does not guarantee shared interpretation of the discourse's social import. Hymes (1968), meanwhile, in a survey of linguistic and anthropological literature, assembled a massive array of counterexamples challenging the Herderian assumption that common language reveals common ethnicity. Only in ideology must linguistic and ethnic boundaries coincide.

In the course of these arguments, Hymes and Gumperz sifted through some aspects of language and speaking that had often been assumed to coincide, yet (as they showed) could vary quite independently of one another. These distinctions must remain important in any adequate account of the social setting of linguistic practice:

- knowledge of a code (or, linguistic variety); i.e., the ability to interpret the denotational and predication value of a symbolic system;
- behavior – the deployment of that code;
- claims to affiliation with a code, and claims to knowledge of it;
- knowledge of 'rules of use,' i.e., understanding the social distribution and appropriate deployment of codes.

Thus one might claim affiliation with a language one does not speak, as did an Italian-American student of mine who wrote a paper entitled 'Why can't I speak my language?' The Yana woman of Sapir's day could interpret all the forms of 'male speech' even if she never uttered them. (Actually, she might utter them if she quoted a male character while telling a story; but she would not produce these forms while speaking in her own social persona.) And rules of use may distinguish among addressees and contexts, even if the addressee does not reply in the same code – as when I reserve a special way of speaking for my pet cat's ears alone.

The recognition of linguistic diversity and its engagement with the structuring of social relations opened up vast areas of sociolinguistic research. As that research proceeded, however, and the sociolinguistic conception of speech community was to be operationalized, new questions arose. In particular, if speech communities are supposed to be objects of empirical description, how are they to be identified? If the community is delimited by some radius of shared knowledge, exactly what is shared? How much knowledge must be shared, and by whom? Recognizing that 'shared knowledge' can never be all-inclusive, Gumperz proposed that what the speech community shared was knowledge relevant to some

significant number of social situations. But what is a significant number, and what makes a social situation significant? Consider, for example, gender-segregated initiation systems where initiates learn special linguistic varieties – such as male initiates in Walbiri and other societies of aboriginal Australia. Perhaps Walbiri women were aware that such varieties existed, but they were in no position to control them, or even to know the details of the appropriate situations of use. Some kinds of knowledge depend on a person's position in a social structure and access to situations in which a particular code is used.

To address this problem, one might envision a hierarchy of speech communities, or overlapping communities, depending on the scope of shared knowledge. In a study of creole language use in Guyana, Rickford (1986) pointed out that the ability to recognize linguistic indices of broad social categories was shared not only within the community of Cane Walk but also within larger communities, even in the whole country, while more subtle sociolinguistic meanings were known only more narrowly. The difference in social scale involved not only a difference in the amount and delicacy of sociolinguistic knowledge but also a difference in evaluative schemata. But if the 'speech community' is taken to delimit the social unit within which linguistic diversity is socially constituted and accounted for – an empirical object that is also the locus of its own explanation – rather than marking the bounds of a particular study with specified goals, then speech communities may well seem to be discrete units, although it is only the researcher's approach that makes them so. It is tempting, moreover, for researchers to slip back into older notions of 'community' and to take a village, or an ethnic group – or a village as localized instantiation of ethnicity – as the sole unit of description.

Finally, how does one investigate knowledge, and how does one determine whether knowledge is shared? To what extent is the relevant knowledge available to conscious articulation, or is it embedded in practice? It is all too easy to take a few informants' claims as being an analysis of the relevant groups, varieties, and uses of language – and so to mistake a particular participant's ideology of language for a description and analysis. One solution has been to abjure informants' explicit analyses, except insofar as they identify some locality or grouping, such as a town or a neighborhood, within which to describe linguistic practices. This is the approach taken by Labov and his followers, who emphasize empirical reliability via consistent interview protocols and representative samples of community members. Labov's

speech community (1972: 120–121) is defined not by members' producing the same linguistic forms in the same way, but rather by "participation in a set of shared norms; these norms may be observed in overt types of evaluative behavior, and by the uniformity of abstract patterns of variation which are invariant in respect to particular levels of usage." While 'shared norms' may suggest shared ideas and values, what looms larger in Labov's work are norms of use (statistical norms). It is the patterns of linguistic variation – i.e., overlapping patterns of usage, within a controlled sample of contexts – which he puts forward as the crucial evidence of participation in the speech community.

The speech community described in Labov's most recent book (2001) is Philadelphia, represented by samples of speakers from five neighborhoods and a random sample from the city telephone directory. These samples do not actually represent the city, however, because they were purposely restricted to American-born whites. Other speakers, including Philadelphia's large African-American and Latino populations, are excluded because, Labov argues (2001: 506), they do not share in the same patterns of linguistic variation. The purpose of the study, and rationale for the sampling decisions, was to explore linguistic change in the local vernacular English, not to describe all linguistic practice in the city. The question remains, however, as to whether the presence of nonwhite and nonnative speakers is or is not relevant to currents of change.

Observe that this 'speech community' is defined in terms of sharing in a particular pattern of language use – a single 'local vernacular' whose manifestation varies principally in whether a speaker is leading or lagging in its ongoing currents of change, and whether the speech situation is such as to reveal the vernacular most clearly. These variations distinguish among genders and socioeconomic classes within the set of native white Philadelphians, but it is only in that sense that they describe linguistic diversity. Whatever analysis one might envision of the linguistic practices of the city's broader ethnic and racial composition – an analysis that would need to consider multilingualism, multidialectalism, and the social organization of exclusion and avoidance – is precluded from this approach and this conception of 'speech community.' (One might ask, however, whether 'community' is the best rubric for the larger analysis.)

These questions about boundaries, sharing, and the relationship of meaning to practice have given rise to some alternative formulations of the object(s) of study. By the mid-1980s, ethnographically oriented scholars were beginning to reconsider the social theory underlying then-current analyses of linguistic

repertoires and social actors, and to rethink concepts such as 'community' and 'class.'

Speech Networks and Communities of Practice

In a large city it cannot be taken for granted – as indeed it should not anywhere – that the social ties most relevant to linguistic practice are geographically concentrated. Residence, work, recreation, and other activities may be dispersed, and one person's set of social contacts may differ from another's. Network analysis, an approach first developed in urban anthropology and sociology, tracks the webs of personal relationships wherever they occur, starting from an individual and that person's interlocutors. The analysis collates and compares such person-anchored networks and considers how they may reflect or influence linguistic practice. For example, networks may be relatively closed (members have more contacts with each other than with outsiders) or relatively open (less overlap among individuals' social ties). In an early use of the network approach, Gumperz (1964) argued that these properties of networks accounted for differences between the linguistic repertoires of two communities, one in India and one in Norway. Another way to compare networks concerns whether ties are strong (multiplex – an individual has many kinds of relationship with the same person) or weak (relating to the other person in only one situation). Lesley and James Milroy (1992, and elsewhere) have proposed – initially from research on linguistic variation in spoken English in inner-city neighborhoods in Belfast – that close-knit networks with many multiplex ties foster linguistic conservatism, while weak ties are vehicles of linguistic change. Emphasizing close-knit networks' importance as the site of (emergent) shared experience, Gumperz and the Milroys have linked them with notions of 'community,' although Gumperz also calls open networks 'communities' and maintains they still hold something in common.

A related construct is the 'community of practice,' a grouping that is based on participation in some activity or project (*see Communities of Practice*). As with network analysis, the point is that any 'shared' understandings are accounted for as products of joint experience and coconstructed relationships. As Eckert and McConnell-Ginet write (1992: 464), "ways of doing things, ways of talking, beliefs, values, power relations – in short, practices – emerge in the course of this mutual endeavor." Participation in the activity, and members' definition of it, distinguish this grouping from older notions of community. This approach is especially useful, the authors find, for studying

gendered language practices. Because activity-based groups such as football teams, armies, and boards of directors are likely to have a predominantly male membership, while secretarial pools and aerobics classes mainly draw women, these groups' distinctive linguistic practices easily become associated with gender (Eckert and McConnell-Ginet, 1992: 472). A focus on community of practice asks how an activity, a group, an individual as participant, and the meanings of linguistic practices mutually constitute one another.

Both these constructs, speech network and community of practice, suit a social theory in which 'community' is not assumed *a priori*; instead, it has to be achieved. Recently, Duranti (1997: 82) defined the speech community itself in this vein, as "the product of the communicative activities engaged in by a given group of people" – and the work of Ochs, Duranti, and their associates has emphasized the detailed study of activities and social interactions as communicative practices. This emphasis on the emergent character of social relations and the understandings connected with them resembles the ways many anthropologists have rethought the concept of 'culture.' Where older concepts of speech community, in their focus on the distribution of knowledge, presented a relatively static picture in which knowledge was unaffected by the action that applied it, discussions of community of practice and speech network permit a view of culture as public, negotiated, and located in interactional space rather than in a sort of mental museum.

Ideologized Representations and Imagined Communities

Eckert's mention of meaning and beliefs reminds us that sociolinguistic 'knowledge' is not just a tape recording of utterances, but an ordered, cognized, and filtered set of representations. Our interpretations of the linguistic practices around us depend not only on what is actually said, but also on stereotypes we have built up out of our experience – built and (re)configured (Agha, 1998; Irvine and Gal, 2000; Silverstein, 2003). Thus, in a discussion of honorific language in Tibetan, Javanese, and elsewhere, Agha shows how speakers' ideologies of deference, social hierarchy, and linguistic 'purity' lead to asymmetric distributions of linguistic forms across social categories – aristocrats and peasants, for example, deploy different constellations of forms – and these usages yield, in turn, stereotypes of speaker identity and rank (Agha, 1998: 166). Although Agha and Silverstein emphasize that the stereotypes are based on evidence – grounded in participants' discriminable experiences of language use – the

stereotypes can also overwhelm the input, influencing the interpretation of utterances that do not precisely conform to them. Since people's experiences differ, and since interpretations also reflect the interpreter's position in society – and these differences pertain even to coparticipants in a particular activity group – cultural stereotypes and sociolinguistic knowledge cannot be perfectly 'shared.'

The object of study in this line of research reaches beyond the immediate. Distinguishing between representations that are experience near and those that are experience far, we must explore the latter in their own right. The people I imagine as co-inhabitants of my social world, including those I envision as past and as potential interlocutors – as well as those I know I will never meet and those I hope to avoid – are a population not limited to the history of my actual contacts. A recent strand of research on speech communities has considered these distant and imagined relationships. For example, Spitulnik (1996) examined the role of Zambian radio programs, whose audience may imagine itself a community of shared listening practices. In the circulation of 'public words,' such as catchphrases from well-known programs and announcers, listeners repeat the expressions that show their familiarity with the broadcast, and so constitute a colistenership with people they have never met. 'Hello Kitwe?' – a channel-checking expression with which the broadcaster based in the Zambian capital tries to transfer operations to a broadcaster based in the provincial city Kitwe – when repeated in a crowded shop by a customer trying to get attention, arouses knowing smiles in other customers who recognize the phrase (Spitulnik 1996: 168).

The social groupings defined by the circulation of 'Hello Kitwe,' and by a radio broadcast's audience (actual or potential), are perhaps more often counted as 'publics' than as 'communities.' The terminological difference stems from the impersonal character of the 'public,' which is linked to its potentially large scale as an arena of communication and signals its connection with political institutions. As Gal and Woolard (2001: 1) wrote, "the work of linguistic representation produces not only individualized speakers and hearers as the agents of communication, but also larger, imagined social groupings, including ... publics. Such representational processes are crucial aspects of power, figuring among the means for establishing inequality, imposing social hierarchy, and mobilizing political action." Our lives, including many aspects of linguistic practice, are affected by these representational processes and the actions they lead to, sometimes at a considerable distance.

Notice now that the publics imagined from different social standpoints may not define the same sets of people, and may fail to coincide with any concretely traceable social network. Zambian policy makers, like many others in Africa, distribute radio broadcasting – schedules and topics – among seven 'official Zambian languages' plus English, according to a model that equates language with ethnicity and region. Since most listeners are multilingual and some languages far outreach the ethnic populations they supposedly identify, actual audiences for a program are often quite different from the ethnic communities imagined in radio policy. Of course, the propensity to identify (homogeneous) language with ethnicity and region has a wide distribution and a long history, taking us back at least to the Herderian formulations mentioned early in this article. The same kind of equation underlies Benedict Anderson's otherwise brilliant discussion (1991) of the nation as 'imagined community' – imagined as the readership of newspapers and novels published in standardized languages and distributed via the mechanisms of print capitalism. As if it were an ethnic group writ large and mediated by print capitalism, this 'community' resembles the Saussurean homogeneous speech community in that Anderson assumes the population is monolingual in 'their' language, whose slight phonetic variations do not interfere with reading. This community is doubly imaginary, then – in its members' imagination and in Anderson's. It exists only in an ideology that imagines the standardized language of the nation-state as the common natural resource of its citizenry, so that linguistic diversity is interpreted either as something trivial, or as deviance and inadequacy. Images of the nation, and of the 'authentic' citizen, are at stake.

A good example is the debate over an orthography for Haitian Créole/Kreyòl (Schieffelin and Doucet, 1998). The spelling of the language's name illustrates the problem: the contest between those who see 'Créole' as fundamentally French – and speakers of standard French as the most authentic citizens – and those who see 'Kreyòl' as fundamentally other. The authors ask (1998: 303): "What is the real, authentic kreyòl? Thus, who is the real, authentic Haitian – the dominated 'Africanized' masses or the dominant 'Frenchified' elites? Is there a 'pure' kreyòl? ... The sound system leads directly into the core of the debate about social classes, legitimacy, and authenticity."

Those who reject the Herderian formulation of language-based community must nevertheless recognize its prevalence in many parts of the world as the ideological grounds for political, territorial, and other kinds of claims. Silverstein (1996, 1998) therefore distinguished between 'language community,'

which is based on its population's allegiance to norms of some 'shared' specified denotational code (such as a prescriptive standard) – conceived as 'their language' – and 'speech community,' based on indexical facts of repertoire deployment and their associated norms of use. The distinction recalls our two earlier threads in the conception of 'speech community,' the Saussurean and the sociolinguistic, but it places the former in the realm of ideologies of allegiance and the latter in the realm of situated experience. Although this pluralistic view of community is appropriate for many kinds of analysis, Silverstein (1996) showed its particular utility in understanding the dynamics of language contact in North American ethnohistory. The spread of European languages and their eventual dominance over indigenous ones took place within local settings which had varying social histories and shifting allegiances.

This analysis depends on looking at social (and linguistic) relationships of different kinds and on different scales. In the contact zone, indeed anywhere, 'language community' and 'speech community' do not identify the same population. Yet, the social dynamics of each kind of community affects the other. As Silverstein (1998: 401) put it, they are dialectically constituted cultural forms. Moreover, localized forms of speech and local social ties are in a similarly dialectical relationship with larger-scale, even global, currents. The proponents of *francophonie*, for example, must contend with local social dynamics and multilingual scenes, while populations in localities as disparate as Québec and Rwanda contend, in turn, with *francophonie*'s language-based claims to their allegiance. The 'local' is itself an emergent construct, produced in relation to larger-scale processes. In sum, speech communities and language communities are different; neither stands alone; and an account of either must look outside its bounds.

The View across the Boundary

Questions about the speech community's boundary have already been raised with respect to the scale of analysis – a gradient in which face-to-face social groups, where everyone knows a great deal about everyone else, are embedded in larger settings where people are less well acquainted or not actually encountered at all. The question of boundaries is not just a matter of scale, however, but also of opposition. If, for example, boardrooms and Tupperware parties define different communities of practice and if they are associated with gender, then their relationship is one of opposition, not merely of random difference. And while it could be argued that gendered practices, however divergent they might be, are nevertheless

part of some larger 'community' whole, any community X is only identifiable in relation to some population that is not-X. Even in face-to-face interaction, the participants establish their distinct identities as well as their commonalities.

Interaction is thus as much a process of differentiation as of accommodation. The crucial question is what kinds of differentiation and accommodation are produced, and by what semiotic means, in each empirical case. A similar question was asked decades ago about the signs distinguishing different ethnic groups. In *Ethnic groups and boundaries*, Frederik Barth argued (1969: 10) that "ethnic distinctions do not depend on an absence of social interaction and acceptance." Instead, the persistence of an ethnic boundary depends on people's defining themselves in opposition to others whom they know. Similarly, Labov's classic research on Martha's Vineyard showed that the residents' speech forms were being reconfigured because – after the island's economy shifted away from fishing and toward the tourist trade – the contrast between native islanders and visiting mainlanders increasingly outweighed the islanders' internal divisions. Apparently, the Vineyard dialect was diverging from mainland speech because of, not in spite of, increased contact.

Following these precedents, Irvine and Gal (2000) argued that attention to boundaries and processes of differentiation should replace the concept of 'speech community,' which was overburdened with problematic baggage. Descriptions framed in terms of the 'speech community' tend to privilege a particular scale or type of social organization and to preclude exploring relationships that extend beyond its boundary. Moreover, many scholars now disavow the consensus-based social theory that underlay much earlier sociolinguistic and linguistic discussion of 'community' and discouraged attention to processes of exclusion, conflict, and domination. Rickford and the Milroy & Milroy, for example, have proposed that conflict models of social class account better for the observed patterns of sociolinguistic variation than the consensus model can. In a related vein, Morgan (2003) argued that "speech communities are recognized as distinctive in relation to other speech communities. . . . They come into collective consciousness when there is a crisis of some sort, often triggered when hegemonic powers consider them a problem. . . . Speech community represents the location of a group in society and its relationship to power." This emphasis on crises and power relations external to the community is borne out in Morgan's writings on the discursive practices of African-Americans, especially women.

Social life includes both agreement and conflict, sometimes both at once. In our joint work, Susan

Gal and I have tried to capture this complexity by focusing on (linguistic) differentiation as a semiotic process that accommodates, but does not in itself entail, contestation. This complex process, we argue, includes a principle of fractal recursivity: an opposition that has been understood at one level of relationship can be projected onto other levels, yielding subcategories and supercategories. Thus the same process accounts for the possibility that linguistic varieties, social identities, or any other sociolinguistic formation may sometimes be seen as (sub)divided, but sometimes as unified. For example, in research on rural Wolof speech patterns I have proposed (Irvine, 1990) that a principle which (ideologically) distinguished the speech of high and low Wolof castes applied recursively. Applied within the high caste it marked subtler distinctions of rank; applied between languages it distinguished Wolof from French, to the latter's disadvantage.

We focus on differentiation because difference and distinction are what makes possible the logic of relations on which society and language depend. Just as Jakobson and Sapir showed for language, society too consists in relations and fields, not things. A focus on 'community' that does not look across the grouping's boundaries tends to obscure the relational logic that organizes a social field, by overemphasizing what people have in common and treating its object of study as an autonomous thing, rather than an artifact of the researcher's approach. No community is an island.

Conclusion

Researchers investigating the relationships of language, culture, and social life need ways to think about the social aggregates in which those relationships are located. Most authors refer – whether loosely or rigorously – to some sort of 'community.' As we have seen, however, definitions of 'speech community' have varied widely, and many scholars now argue that it cannot be entirely self-contained as an object of study. Just as most anthropologists no longer see 'culture' as a homogeneous object that can exist in isolation (and should not be treated as if it did), we realize that speech communities are related to other social formations that intersect with them, or are incorporated within them, or contrast with them, or include them. A crucial step away from the speech-community-as-ethnic-island approach is to see language community as distinct from speech community, and the two in dynamic relationship – a step that puts the Herderian formulation in its (ideological) place.

Nevertheless, the word 'community' invokes an aura of consensus and common cause, even if you

try to define it in some other way. It is tempting, therefore, for 'community' – whether researcher's or participant's construct – to conflate, or slide among, at least three quite different axes of relationship: homogeneity and difference, consensus and conflict, solidarity and distance. Just as difference is not the same thing as conflict, so any conflation of homogeneity, consensus, and solidarity under the rubric of 'community' is misleading. It is all the more so when language is added into the mix, as if languages were based upon – or could produce – these qualities of community. These issues ought to be disentangled.

Even if its technical utility is limited, however, 'community' is a term it is hard to do without. Its various formulations each address something of interest as to how the practices that make social relationships rely on systems of signs. Although the scholar who looks for standardized off-the-rack technical terms will not find one here, there is much to be gained from exploring the surrounding debates.

Speech and Thought: Representation of

M Toolan, University of Birmingham, Birmingham, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

This article addresses the Representation of Speech and Thought (henceforth RST). The overwhelming focus will be RST in literature, but many of the principles can be extended to the representation of speech – and even of thought – in other varieties and genres: journalism, records of parliamentary debates, commissions of inquiry and committees, police interviews, etc. Still it is worth noting at the outset that literary representation of speech and thought emerges from the potential in all written languages – a potential of inestimable value – to record ('capture', render inspectable) in semipermanent form (hence usable at

later times and in different places) what someone said at one particular time and place. More remotely yet, written records of speech must derive, as a counterpart, from the reporting of others' communicative acts that is so important a part of spoken and sign languages.

RST is therefore bound up with writing rather more than is always acknowledged. Younger readers, fully of the digital age, may be puzzled that these opening remarks about the power to record or represent speech are not focused on audiotape recording and digitized sound files, now very widespread means of representing speech. But this article is about an affordance of the much earlier and more culture-changing technological breakthrough, the development of writing, and literary authors' rich repertoires of means for presenting characters' words on the

page. Little further mention will be made of Internet literature or Web-based fiction; but it may be noted in passing that modern technology is such that there is nothing to stop a Web-based fiction writer from using sound files for some or indeed all of the discourse categories shortly to be described (characters' direct speech, indirect speech, narratorial discourse, etc.). One literary format of increasing importance that might here merit further comment is the audio novel, widely used by travelers and the print-weary: typically using just one performer as teller, they deserve fuller study to see how they resolve the tricky problem of conveying direct speech and the narratorial forms distinct from each other. And then how do they cope with those passages of FID or combined discourse (to be described later), where the voices of narrator and a character are impossibly mixed or calqued? Nowhere do Bakhtinian ideas of the polyphony or clash of voices seem more palpably applicable. The potential 'reoralization' of the written genres of the novel and the short story, triggered and sometime perhaps prompted by the spread of audio-books, may come to require extensive scholarly treatment.

RST, then, comprises some processes for the partial simulation of speech or thought that have emerged in written language. A general caveat at the outset: this article focuses on and takes its examples from literature in English, although there is no reason to suppose that RST and its subtle subtypes do not flourish in all the languages with a developed literary tradition; certainly it has been extensively studied and discussed in most European languages, and cross-linguistic studies are increasingly proposed, where much of the interest lies in comparing and contrasting the formal exponents of distinct subtypes (in particular the tense-aspect requirements in FID) and indeed whether certain subtypes are prominent in one literature while nonexistent in another, or developed much later, and so on.

Direct Speech and Indirect Speech

Direct Speech

"My dear Mr. Bennet," said his lady [Mrs Bennet] to him one day, "have you heard that Netherfield Park is let at last?"

Mr. Bennet replied that he had not. (Jane Austen, *Pride and prejudice*, chap. 1)

In the canonical forms of both direct and indirect speech today (henceforth DS and IS, respectively), a fundamental distinction is made between the reporting or inquit clause, in which the speaker of the reported material is identified and cast as the subject of a verb of communication, and the reported clause,

in which that speaker's message is presented. The reported clause of direct speech is usually set off, by speech marks at its boundaries, from the reporting clause; and sentence-initial reporting clauses may be followed by a comma or colon. The reported clause is understood to give the speaker's actual words, *verbatim*, hence all the deictic elements (pronouns, tense, time and place expressions) within the clause or fragment reflect the speaker's deictic center, at the time of speaking, as in Mrs Bennet's speech. Here, the present tense is used for events/states that are true at the time of Mrs Bennet's speaking, she denotes herself by first-person pronouns (here *my*) and her addressee by second person pronouns, and all evaluations (*My dear ... at last*) are entirely hers. Mr Bennet's reply is rendered in IS – which specifically denotes the segment *that he had not* – and this, like the reporting clause *Mr Bennet replied* that precedes it, is wholly based on the narrator's deictic perspective and as a result uses a third-person pronoun to denote the reported speaker and past tense. Various DS features are difficult or impossible in IS; here, for example, if Mr Bennet had echoed his wife's formulaic endearment this would be problematic within an IS construction:

? Mr. Bennet replied that (his) dear Mrs Bennet, he had not.

Terms like 'difficult' and 'problematic' are often applied here, where in canonical DS and IS the linguist is usually quite prepared to specify what is grammatical or ungrammatical. The manipulations of what is possible or acceptable in variant free forms of IS (in modern English at least) make firm grammaticality judgments particularly difficult in this area.

The reporting clause in DS can follow the reported speech, and in such cases there is scope for inversion of the verb and (usually) nonpronominal subject in the reporting clause. Or the reporting clause is 'flanked' on either side by direct speech:

"Kitty has no discretion in her coughs," said her father; "she times them ill." (*Pride and prejudice*, chap. 2)

In present-tense feature-article journalistic reporting, such inversion within the reporting clause is frequent and possible even where that inquit clause comes first (again, provided the subject is nonpronominal):

Adds Smith, "The key to utilizing a mammogram to its fullest potential is by getting a high-quality screening performed by a competent clinician" (*USA Today* 19 July 2001)

Although opening and closing inverted commas remain a standard marker of direct speech in all

written varieties, many 20th-century fiction writers dispense with them, instead marking the onset of a character's turn of talk by a new line, an indent, and a long dash. But for those writers who retain reporting clauses with direct speech, it is important to note that they provide more than a perfunctory speaker-attribution: they often carry information about the speaker's emotions or attitude and may include information about gesture, facial expression, or body movement, all of which may be evaluative or indexical.

Indirect Speech

Whereas DS supplies the reported speaker's actual wording, IS relays only the content, gist, or illocution of the actual or implied DS utterance (implied in all cases of fictional IS, where there is no actual DS precursor). In indirect speech with a sentence-initial reporting clause, no graphic devices set off the reported material from the reporting clause, but the reported clause is introduced by a complementizer or subordinator (commonest is *that*, as in the Austen sentence above: *Mr. Bennet replied that he had not*). Where the reporting clause comes first, as in this example, complementizing *that* is often ellipted (cf. obligatory *que* in comparable French constructions), whereas more semantically specific ones cannot be: *if*, *whether*, and *wh*-words introducing indirect questions and exclamations. In the case of IS reports of requests and other directives, *that* may or must be replaced by an infinitival construction, with raised reported clause subject: compare *She asked that he shut the door* / *She asked him to shut the door* and *She told him to leave at once* / **She told that he leave at once*.

The reported clause gives a version, and not the precise wording, of the original speaker's utterance, but all deictic elements now conform to the spatio-temporal coordinates of the narrator or reporter, already responsible for the reporting clause. Thus the original speaker of the reported clause is now denoted by third-person pronouns, and time and place expressions are to be interpreted relative to the narrator/reporter.

- (1) Mrs Bennet asked whether he had heard that
Netherfield Park was let at last.

The grammar of IS entails a wholesale adoption of the deictic orientation of the narrator. All deictic indicators that might appear in a character's direct utterance, keyed to the character's assumed point in space and time (in addition to tense and personal pronouns, words like *here*, *today*, *this*, and *now*), will be displaced by deictic indicators, which makes

sense from the narrator's perspective (typically, the 'nonproximate' deictic forms: *there*, *on that (same) day*, *that*, *then*). Among the deictic indicators must be included the use in DS of a few verbs of specific directional movement, implying movement toward or away from the speaking character (*Come here!*; *Go away!*); by contrast in IS the movement verbs will be directionally nonspecific or, like other deictic elements, oriented to the narrator.

Although DS and IS are in a sense equivalent and -alternative forms, there are also asymmetries involved, particularly in fictional and literary contexts. For example, normally a conversational utterance will have just one DS form, but may have several IS versions, varying from each other in minor ways. Compare (1) above with other IS versions, (2) and (3):

- (2) Mrs Bennet asked whether Mr Bennet had heard
that Netherfield Park had finally been let.
(3) Mrs Bennet asked her husband whether he had
been told that someone had finally taken
Netherfield Park.

By the same token, when contemplating an IS sentence, several distinct possible DS versions can be proposed, without any certainty as to which if any was the actual source: any of (1), (2), or (3) could 'derive' from the following (among others) rather than Austen's actual formulation above:

- (1)' Mrs Bennet said "Have you heard that
Netherfield Park has been rented at last?"

It should be stressed that such variations of 'source' (DS) or of 'derived' (IS) forms are particularly associated with fictional narrative (where, for example, there simply is no actual DS counterpart of the IS construction that the writer has composed). In non-fictional contexts, the *vraisemblance* or 'faithfulness' standard may be set much higher, so that IS reporting of speakers may be required or expected to match closely the wording of the real DS source, to limit misrepresentation. In extreme cases or genres (e.g., when giving witness evidence in a criminal trial), IS may be disallowed.

When contemplating Direct Speech (and to diminishing degrees when considering each of the other forms to be discussed in this article), at least two binary distinctions need to be considered: is the text in which it appears literary or nonliterary; and is it hypothetical or actual (e.g., fictional DS may be used in philosophical and moral arguments). On that basis we can distinguish DS in novels and in philosophical arguments, letters recording personal experience, and hard news journalism or Hansard-like parliamentary

records. The literary-and-actual is a less-exploited category, but there are enough novels that incorporate if only fleetingly famous individuals and some of their reliably documented utterances for this to be a real category. What distinguishes the nonliterary and actual from the literary and the hypothetical is that there is some process of transcription prominent in the former, and by contrast some kind of invention prominent in the latter (although neither variety is *purely* transcriptional or inventive).

Some Major Points of Difference between Direct and Indirect Speech

Indirect discourse maintains the tense of the encompassing narrative (in traditional English fiction, this is past tense; in some contemporary literature, this may be present tense). Direct discourse is in present tense, the norm for natural conversation of which it is a simulation. First- and second-person pronouns in the direct version, denoting the speaking character and their addressees, contrast with gender-appropriate third-person pronouns in the indirect version, being the narratorial designations of those characters (a large exception to this are those stories where the narrator is also a story participant and is accordingly designated within the story by first-person pronouns; a rarer exception are 'you-narratives'; but even in these exceptions, the pronouns denoting addressees, in the former case, and those for seemingly representing the narrator, in the latter case, diverge from the direct I-you pattern. The two patterns are *I-him/her/them* and *you-[all accusative forms]* respectively. One general upshot is that English indirect forms are more explicit than the direct ones with respect to the gender of the addresser and addressee.

It has been traditional to describe the reporting and reported clauses in DS and IS as syntactically related to each other differently; in typical IS where the reporting clause comes first, they are syntactically related hypotactically, with a clear sense of matrix and embedded clause; but in DS the relation is paratactic, with the reported clause as nonembedded complement. But the most suitable grammatical description is certainly a matter of debate (see Huddleston and Pullum, 2002: 1023–30, for arguments). But it is clear that 'robustly paratactic' DS constructions, such as imperatives and exclamatives, resist incorporation into IS format. Thus when in Joyce's 'The Dead' Mr Brown takes a first sip of his whiskey and the text runs (using DS):

-God help me, he said, smiling, it's the doctor's orders.

it is hard to devise a truly plausible IS version:

?/* He smilingly cried that God should help him but it was the doctor's orders.

?/* God would help him, he said, it was the doctor's orders.

None of the 'colorful' idiosyncratic and dialectal qualities of the speech or thought of a character who is reported directly survive the transfer to a canonical IS version; the speech undergoes a kind of translation, into the language of the narrator, and the latter is conventionally (but not obligatorily) 'standard', 'neutral', detached, a superior knower even if they do not assert 'omniscience'. The narrator is sole authority, solely responsible, for the wording of both components, reporting and reported, of the IS construction. By contrast there is an explicit division of authority in DS constructions, with the reported speaker solely responsible not merely for the sense but also the actual wording of the reported material.

Still, it is worth emphasizing that what is certainly lost, in IS reporting, is not 'colorful language' necessarily, but 'the *character's* (possibly colorful) language'. That is to say, typically and conventionally, especially in literary fiction, narrators are more 'neutral' and formal than the characters of whom they tell. But this is only a convention or pronounced tendency and will be overridden in many particular cases. One is the novel *The adventures of Huckleberry Finn*, where Huck himself, as first-person narrator, reports nonstandardly the presumably standard speech of some of the protagonists in his story.

A Minor Variant of Direct Speech: Free Direct Speech

Where direct speech is presented without accompanying a reporting clause, it is given the more specific label free direct speech (FDS) by some analysts. In just this respect (lack of the reporting, inquit or 'framing' clause), FDS is like FIS, but in other respects it is really only a variant of DS (no difference is assumed or demonstrable between the exact content of DS and FDS versions) and not an independent category as the free indirect ones are. Reflecting its status as a variant, there are only slightly different functions or effects achieved by FDS that are not achieved by all DS. An alternative conceptualization would be to note that, unlike IS, the *inquit* clause is not essential or integral to a direct speech report, and that therefore those direct speech reports with a framing clause are the supplementary variant (ADS – attributed direct speech, in contrast with the unattributed form, which might now be labeled simply DS).

Often in cases of FDS the reporting clause is as close as the adjacent sentence. Or one reporting

clause introduces (hence has 'scope' over) a series of (distinct) utterances from an individual, so that the technically FDS sentences are so created for purposes of textual economy as in ellipsis cohesion. More interesting may be sequences of FDS dialogue, typically between two parties (metronomic speech), where speaker change and speaker identification must be inferred by the reader, and with less than full certainty. Where DS has the reporting clause following, some analysts label the speech FDS, by analogy with parenthetical framing clauses in FID (see following).

Free direct speech may also be exploited to give the impression of rapid interchanges (as in fictional dialogue in Hemingway, Ivy Compton Burnett, etc.). Constructions that have the appearance of DS are widely used in print newspaper headlines (particularly tabloids), although it often transpires that the 'speech' is the creation of a copy editor who has rephrased one participant's most forceful remarks in more pithy and dramatic style or has synthesized the more subtly expressed views of several protagonists. By convention strict fidelity to the speaker's precise words is not always expected or required, but misrepresentation and trivialization are recurrent risks in this pursuit of entertaining, sales-generating copy.

NRSA and NV

Two categories have been proposed (by Semino and Short, 2004) as lying at the most indirect end of the speech representation continuum: these are NRSA, narrative report of speech acts, and NV, narrator's representation of voice. The former, a more established and accepted category, equivalent to what McHale (1978) called 'diegetic summary', covers those reports of speech in which the content is severely abridged (to the point where arguably there is no genuine speech representation) but a scant indication of the type of illocutionary or perlocutionary force of the act is provided:

All evening they argued and quarreled over how best to economize.

Mary's father stepped in with congratulations. (Graham Greene, *Brighton rock*, p. 137)

As the most indirect form of speech representation, NRSA is a useful device for novelists who wish to keep firm control on the narrative, but at the cost of creating a non-scenic detachment from the living voices of particular speaking characters. NRSA is suited to an aggregative and abridged recording of views, particularly where these are in broad agreement, as in summarizing the view of a committee or even a large meeting

[For hours] 8,000 hunt supporters ... made themselves heard ... They vowed to go on protesting until the government reversed its plan to ban hunting with dogs. (*The Guardian*, 29 September 2004)

Whereas in NRSA utterances one arguably reaches the limit of speech representation, often with only a slight indication of the actual wording of the anterior speech, with NV (narrator's representation of voice) attention has turned away from representation altogether, to simply reporting that the activity of talking has occurred. NV covers those occasions where the narrative reports that an individual spoke, but "we are not given any explicit indication as to what speech acts were performed, let alone what the form and content of the utterances were" (Semino and Short, 2004: 44), or there is "summary reference to speech events that involved a large number of participants" (Semino and Short, 2004: 45). This new category (and even more so its near equivalent in thought-reporting, NI, discussed later) proved useful to Semino and Short, whose interest was in a corpus-based comparative study of frequencies of distinct types of category-use in a corpus of fiction, journalism, and (auto)biography. Two NV examples are given in bold here:

We **exchanged a few words lazily**. (Conrad, *Heart of darkness*, p. 28)

After talks in Belgrade, Mr Milosevic said he fully agreed with the international peace plan. ('Milosevic backs Hurd peace plea', *Guardian*, 5 December 1994)

Free Indirect Speech

A conversation then ensued, on not unfamiliar lines. Miss Bartlett was, after all, a wee bit tired, and thought they had better spend the morning settling in; unless Lucy would at all like to go out? Lucy would rather like to go out, as it was her first day in Florence, but of course, she could go alone. Miss Bartlett could not allow this. Of course she would accompany Lucy everywhere. Oh, certainly not; Lucy would stop with her cousin. Oh, no! That would never do! Oh yes! (E. M. Forster, *A room with a view*, Penguin, p. 36)

At this point we must turn to the phenomenon that alone justifies dwelling on the topic of RST at such length in an encyclopaedia of linguistics – a phenomenon interest in which, as a topic of some theoretical importance to linguistics, was greatly stimulated by German scholars of the *Sprachseele* school and linguists such as Charles Bally and Marguerite Lips in the early 20th century, the latter calling it *le style indirect libre*. Since then this narratological hybrid, lying somewhere between but apart from either the wholly narrated, or the reported, or the direct representation

of speech, has acquired many names in different languages, including: *erlebte Rede*, represented speech, combined discourse, quasi-direct discourse, and free indirect speech (FIS).

FIS is the narratorially most fascinating of styles of discourse reporting, carrying some of the formal features of both character-expressive DS and narrator-expressive IS. FIS is a blending of the IS or narratorial options for tense, pronouns, and graphological non-removedness, but the DS or characterological options in syntax (especially noticeable in interrogatives and imperatives and exclamations), in its dispensing with complementizers, and its adoption of the character's space/time deixis, expressive lexis, and subjective modality.

But FIS is not simply a judicious combination of DS and IS features, nor simply some middle way between these two. Both DS and IS are accompanied by a framing or matrix clause: canonical FIS eschews one altogether (noncanonical FIS, with reporting clause present, is discussed later). Thus FIS is 'a bit of both' DS and IS, but also 'a bit of neither'. FIS styles of speech representation, then, are neither direct nor indirect according to orthodox prescriptions, but mixings or mergings of narratorial indirectness with characterological directness. And despite the earlier comparisons with DS and IS, the mode that FIS most crucially complements or contrasts with is PN (pure narrative: pure in the sense of being the narrator's direct address of the reader, without any traces of the words actually spoken or thought by characters; hence PN is chiefly reports of events and actions, and descriptions). Where uncertainty arises for the reader in the evaluating of possibly FIS phrasings, the confusion is one between character voicing and narratorial voicing. Between DS, IS, and FIS we finally have only variations in the fullness or editedness of rendering of the same individual's voice; but where we cope with the risk of confusing FIS and PN we are in danger of misattributing or misidentifying two entirely different voices and two different individuals, the character and the narrator.

If there is one linguistic feature that seems noticeably more prominent in FIS than in alternative modes of discourse representation, it is modality. FIS is marked by frequent use of modal verbs (*must, should, had to, could, might, would*) and sentence adverbials (*certainly, perhaps, maybe, surely, of course*, etc.) expressing judgments about the likelihood or necessity or desirability of some action or state transpiring. All such modality discloses the character's needs and wants and is frequently woven into contestable judgments. Postponing further discussion of the functions of FIS to a more inclusive section on FID

generally, we turn to cases of indirect speech report with parenthetical inquit verb.

Preposed Reported Clauses: IS or FIS?

Of considerable interest are all cases where the reporting clause follows the reported one, and the latter has the 'backshifted' tense and distal or narratorial deictics that would suggest IS:

Could he accompany her home, he asked.
What an appalling summer she was having, she said.

These are not standard IS: both have, in the reported component, the syntactic inversions of direct questions and exclamations respectively, whereas with framing-clause-first IS noninversion of elements is the norm. Neither of the two cited sentences, if simply reversed, would be regarded as canonical IS, particularly in light of more grammatically unified alternatives. Thus both

He asked could he accompany her home.
She said what an appalling summer she was having.

would be judged nonstandard or dialectal, by contrast with 'standard' IS:

He asked if he could accompany her home.
She said that she was having an appalling summer.

But whereas *He asked could he accompany her home* might be classed simply as nonstandard IS, there are grounds for treating *Could he accompany her home (he asked)* as FIS, the belated reporting clause being processed by the reader only when the reported speech has already been understood to express the words and 'voice' of the character denoted by *he*, albeit expressed within the narratorial deictic regimen. As for the treating of *He asked could he accompany her home* as nonstandard IS, again it is hard to see a definitive formal or criterial basis for specifying where such nonstandard IS shades into some form of FIS (consider more character-expressive versions such as *He asked could he please please accompany her home*).

Returning to the 'standard' IS sentences earlier, with reporting clause first, it is evident that a 'mechanical' inversion of the reporting and reported clauses of the kind possible in relation to DS utterances (She said "I'm lost!" ⇔ "I'm lost!" she said) yields ungrammatical forms:

*If he could accompany her home, he asked.
*That she was having an appalling summer, she said.

To be grammatical, the complementizer must be removed, and subject-verb inversion must apply in the reported question, but those steps move the

reported clauses closer to direct speech, i.e., into the notional territory of FIS, than would otherwise be the case. And like FIS and DS sentences (and unlike those in IS) the reported clauses are also grammatically independent. One is drawn to conclude that where speech is reported using the narrator's tense and pronoun selections and with the reported clause preceding the inquit clause, there is no option of normal IS, and the only reason for withholding the label FIS from such cases would be adherence to the view, as axiomatic, that any within-sentence *inquit* clause cancels free indirect status.

Representation of Thought: Direct, Indirect, Free Indirect

Direct and Indirect Thought

In English literary fiction, all the speech representation categories discussed above have become matched, over the last 200 years or so, by loosely equivalent ones for the representation of thought. Indirect thought was the first to become widespread, but it is convenient to begin with direct thought (DT), which purports to give an accurate record of a character's verbalized thoughts. And like DS, which tends to be far more coherent, free of the repetitions, false starts, and other phenomena reflective of limited planning time than actual speech, so DT also, by convention, denotes a form of thought reporting that observes the norms of sentential grammar (e.g., expressing 'complete' ideas or propositions).

He looked very tall on the darkening grass, and the thought crossed her mind, "He is like a weed." (K. Mansfield, *At the bay*, chap. 1)

She looked up at the pale sky, and all she thought was, "Yes, it was the most successful party." (K. Mansfield, 'The garden party')

DT is used for self-addressed, self-instructing conclusions, at moments of crisis, high emotion, and revelation. In the reporting frame, forms of the verb *think* are commonest, but other verbs and formulations are found, including *say* without a reflexive pronoun. In context, Elizabeth Bennet's words that follow are clearly DT:

With the mention of Derbyshire there were many ideas connected. It was impossible for her to see the word without thinking of Pemberley and its owner. "But surely," said she, "I may enter his county without impunity, and rob it of a few petrified spars without his perceiving me." (*Pride and prejudice*, chap. 42)

Like all thought-reports, DT is indicative of a narrator who is 'intrusive' and even 'omniscient'

(although the suitability of the latter term is now much debated), one who claims and demonstrates exceptional inward knowledge of characters' minds and motives. Even in fiction, 'full' DT with reporting clause preceding is rare; less rare is DT with the reporting clause falling medially (as above) or later, so that the construction is partly or wholly FDT. Unlike Austen in the preceding example, few writers use quotation marks or even an indented new line to mark off the DT from any reporting of its source.

As noted earlier, DT is normally reserved as a label to describe text that represents character-expressive thought, but does so while conforming to the prescriptions of standard grammar, without abrupt fractures or jumps in the flow of structure or sense. Where those constraints seem to be absent, and we feel we are reading a transcript of the mind uncensored and unedited and freely associating, it is customary to refer to this mode as interior monologue (or 'very free' direct thought); literary critics often call it 'stream of consciousness'. In the novels of Woolf and Joyce, and especially in the latter's *Ulysses*, extensive direct thought of this kind is deployed brilliantly, to characterize individuals in all the fecundity and heterogeneity of their thoughts and desires; the mode is exceptionally effective in displaying and dramatizing the depth of human reflexivity – our ability to think about several things at once, to see significance or mutual relevance in disparate things, and to think *about* how we think about such things. Here, for example, is the opening of Molly Bloom's famous interior monologue, which comes at the end of *Ulysses*:

Yes because he never did a thing like that before as ask to get his breakfast in bed with a couple of eggs since the City Arms hotel when he used to be pretending to be laid up with a sick voice doing his highness to make himself interesting for that old faggot Mrs Riordan that he thought he had a great leg of and she never left us a farthing all for masses for herself and her soul greatest miser ever was actually afraid to lay out 4d for her methylated spirit telling me all her ailments she had too much old chat in her about politics and earthquakes and the end of the world let us have a bit of fun first God help the world if all the women were her sort down on bathingsuits and lownecks of course nobody wanted her to wear them I suppose she was pious because no man would look at her twice. (Joyce, *Ulysses*)

Indirect Thought

As in IS, in indirect thought there is a framing or reporting clause identifying the individual who is the source of the reflection, and a following clause of reported thought.

She blushed at the very idea [of accidentally meeting Mr. Darcy], and thought it would be better to speak openly to her aunt than to run such a risk. (*Pride and prejudice*, chap. 42)

Constructions of this form, in the narration rather than within direct speech, with initial reporting clause, are not particularly frequent in literature – especially when one has excluded instances (such as the following, in bold) that in context are IS and not IT:

Mr. Bartell D'Arcy ... praised very highly the leading contralto of the company but Miss Furlong thought **she had a rather vulgar style of production**. (Joyce, 'The dead')

In many constructions, the reporting clause is followed by something – e.g., a preposition – rather than the default subordinator *that*, and this preposition is in turn perhaps followed by a nonfinite clause or only a phrase: *she wondered at ...*, *he thought of the way ...*, *she told herself of*, etc.

He thought of how she who lay beside him had locked in her heart for so many years that image of her lover's eyes when he had told her that he did not wish to live. (Joyce, 'The dead')

In such cases, the passage may be felt to be shading toward the 'more indirect' mode than that of IT, namely NRTA (see later discussion), with its more summarized or rephrased representation of a character's thoughts. As in the cases of IS with noninitial reporting clause discussed earlier, it is often more appropriate to classify as free indirect thought (FIT) those cases of apparent indirect thought report where the reporting clause is medial or final. In the first of the following examples, the FIT status of the bolded words is supported by the fact that in the context the preceding sentences are also clearly Mrs Ramsay's FIT rather than narratorial:

No. He could not say it right. He could not feel it right. **But why not?** she wondered. (Woolf, *To the lighthouse*, Penguin, p. 16)

Odious little man, thought Mrs Ramsay, why go on saying that? (Woolf, *To the lighthouse*, p. 19)

Free Indirect Thought

As in FIS, FIT combines linguistic markers reflective of the narratorial function (such as narrative tense, use of pronouns as if participants are being named from the narrator's point of view) with some or all of the expressive and subjective reflections of the character's voice (here, in the realm of thought, the character's 'inner' voice). Like FIS, the additional absence (in nearly all cases) of a governing,

utterance-initial reporting clause is important. The text therefore has some of the appearance of narrative, but in the detail it is very much a voicing of the character's mentality, in the character's words. And, again, the absence of reporting clause erases some of the impression of clear hierarchy, of an external teller and an observed character being told about. The sense of thoughts being reported is displaced by a sense of thoughts being disclosed, of mental reaction and reflection shown in the course of its being experienced. A very powerful effect of alignment of narrator and character can be achieved, if fleetingly: FIT is, it should be stressed, a relational category: it often draws its strength from its difference from adjacent Narrative, DT, or IT material:

The possibility of meeting Mr. Darcy, while viewing the place, instantly occurred. **It would be dreadful!** She blushed at the very idea, and thought it would be better to speak openly to her aunt than to run such a risk. (Austen, *Pride and prejudice*, End of chap. 42)

It seemed to her such nonsense – inventing differences, when **people, heaven knows, were different enough without that**. The real differences, she thought, standing by the drawing-room window, **are enough, quite enough**. (Woolf, *To the lighthouse*, Penguin, p. 13)

And there is always something necessarily surreptitious and covert about it, by comparison with its neighboring types: the latter through punctuation and reporting clauses and tense and pronoun forms make quite explicit their direct or indirect status, respectively. Like DT, FIT is used for moments of heightened emotion or insight or resolve, but also for moments or thoughts that are implicitly buried deeper within the character's psyche than DT material, and thus less amenable to full-sentence first-person expression – in some cases, sufficiently deeply buried that (we infer) the character will not go on record as explicit source of the thought.

It has become customary to talk of the 'free' in FDS, FIT and so on, as meaning 'free of a framing clause in which who speaks or thinks is explicitly identified'; but in practice one encounters degrees of freedom. On the one hand a parenthetical reporting clause does not govern, syntactically, whatever clause precedes it, and such clauses can have all or some of the word-order, deixis, modality and lexical subjectivity of the character in quasi-direct form, to the point that readers will confirm that the 'voice' or intonation of the character seems to predominate: largely free, then, at least until the reporting clause is encountered. On the other hand many grammatically complete utterances that combine character expressivity with narratorial tense- and pronoun-selections – thus, canonical FIT or FIS – have explicit indications, in adjacent sentences, of the

particular character who is the source of the thoughts or speech: only free very locally, then, and not when cotext is fully taken into consideration. Ultimately those occasions of FID and FDD that are of most interest to literary linguists are those where uncertainty over the answer to the question ‘who speaks here, who thinks here?’ persists even after a thorough rereading – where some ambiguity remains as to whether a judgment or insight is the narrator’s or the character’s, or that of one character and not another. And such uncertainties are often connected to the content and intent of the represented comment or judgment: if this appalling remark was intended seriously it must be from the character, but if intended ironically it is probably the narrator’s. ‘Undecidable’ free forms – particularly free indirect ones – foreground uncertainties in readers’ knowledge of characters and narrator. Consider the following extract, for example, which comes late in Lawrence’s *Women in love*, when a womanservant confirms to Gudrun that her former lover, Gerald Crich, has, as suspected, perished in the Alpine cold. The final sentence seems largely to be the womanservant’s FIT, but it may have something of the narrator’s voice in it, and even something of Gudrun’s own thoughts (as in the preceding Gudrun FIT); and is it not, in a sense, a fair comment on Gudrun?

“Il est mort?”

“Yes – hours ago.”

Gudrun did not know what to say. What should she say? What should she feel? What should she do? What did they expect of her? She was coldly at a loss.

“Thank you,” she said, and she shut the door of her room. The woman went away mortified. Not a word, not a tear – ha! Gudrun was cold, a cold woman. (Lawrence, *Women in love*, chap. 31)

A final remark is in order concerning the importance of forms of thought representation in modern literature, notwithstanding the degree of artifice or counterfactuality entailed in purporting to report the contents of another person’s mind. For although new technologies and art forms have come along, diverting attention away from literature, the latter retains a particular special status as a forum for the exploration and dramatization of consciousness. It is then as much an opportunity as a difficulty that, by contrast with the establishment of DS as the normal way of relaying other’s heard utterances, thoughts are represented in more various ways. Thought is such an amorphous entity, seemingly a cover term for a range of mental activities only some of which are remotely capturable with the linearity of language, that no single format of presentation has emerged as the standard. Many commentators would argue that there can be no such thing as ‘thought transcription’

truly on a par with ‘speech transcription’, and that at best thoughts can be described, not transcribed (just as body movements might be described but not transcribed). Another major distinction concerns genres of use: although speech representation is central to a host of human activities and institutions, thought representation has been largely confined (with exceptions in, e.g., biography and personalized journalism) to the realms of literary fiction. In fact thought representation is a distinguishing feature of modern literature and one of its chief assets; despite all the advances in neurological and cognitive science, perhaps no other cultural form is so powerful at appearing able to make available to us other peoples’ minds, and the unlimited movements of consciousness. High in the roll call of great novelists who have given us, via thought representation, insights into the chaotic architecture of others’ minds and the oceanic storms of emotion and desire that may rage therein are Dostoyevsky, Proust, Joyce, and Woolf. But the examined mental life has been a literary interest since the earliest times, and only became more entrenched, a preoccupation, in the modernist period, roughly contemporaneously with an explosion of interest in psychology and psychiatry ushered in by the work of William James, Freud, and Jung.

Discourse Categories as Superordinate to Speech and Thought Modes

So far in this article, the major categories of speech representation have been discussed separately from those of thought representation, and there are certainly good reasons for doing so. On the other hand, as has been clear in the foregoing, there are many similarities of form, and some of effect also, between the core speech categories DS, FIS, IS, and NRSA and counterpart core thought ones of DT, FIT, IT, and NRTA. Accordingly a useful practice has developed of replacing the terms *speech* and *thought* by a superordinate one, *discourse*, giving rise to a set of superordinate labels (especially DD, FID, and ID), and in the remainder of this article these portmanteau terms will sometimes be used. But it remains true that in the actual reading of a text one encounters not ID but something that is clearly either IS or IT (and only rarely – but interestingly – is assignment of an utterance to the ‘S’ or the ‘T’ scale undecidable). So in analysis the more precise labels are preferable.

Who Speaks, Who Thinks?

In the reading and analysis of literary (and other) narratives, it is often crucial to determine who

is underlyingly responsible for the words – possibly implied to have been spoken, or simply thought – that one encounters. With regard to FIS and FIT, the question amounts to the following: ‘To whom do we attribute these spoken words or articulated thoughts?’ The ‘Who is saying/thinking this?’ question is useful to keep in mind, because FID is a very open category. Despite the foregoing list of usual indicators of FID, there is no single *necessary* feature of FID, which you have to have in order for a phrase or clause to qualify as FID. Narratives in the present tense (where there will be no tense difference between direct and indirect discourses) or with first-person narrators can just as easily contain FID as other types. As Leech and Short (1981: 328–33) show in the following two examples, a single character-attributed expletive, or even a single character-expressive punctuation mark, can in suitable context signal the presence of FID rather than narratorial indirect discourse:

He said that the bloody train had been late.
He told her to leave him alone!

We assume that the *bloody* is the character’s (*He*), and not the narrator’s, and similarly that at least the exclamation mark is the character’s. These examples highlight another interesting uncertainty of FID examples: the lack of a decisive indication of the mode’s extent. Thus in the first example, ‘how much’, before and after the word *bloody*, is also essentially attributable to the character? And in the second example, is the entire clause ‘leave him alone!’ FID, or only ‘alone!’, or merely the exclamation point?

Finally, how all-encompassing should FID and similar discourse-representing categories be conceived to be? A traditional distinction (from Genette) has proposed separate answers to the questions ‘Who speaks?’ and ‘Who sees?’, the former giving rise to the range of speech and thought presentation categories, the latter being addressed by specification of various kinds and degrees of focalization. But this division is by no means universally accepted among narratologists and stylisticians. It is so often the case that, for example, FIT goes hand in hand with focalization from the viewpoint of that character, that it seems that only in exceptional cases are the two noticeably distinct or held apart. Or some have wondered whether all cases of focalization as encoded or expressed in the text cannot be reinterpreted as kinds of FID. On the other hand those who argue that it is useful to address focalization choices separately from speech and thought presentation ones are also, in effect, arguing for a more delimited notion of ID and FID; they maintain that we should not

include, under ID or FID, cases of narrative report that adopt or express only the character’s spatio-temporal viewpoint, their orientation, without any of the character’s (outer or inner) words.

Testing for FID

Two simple framing or commutation tests can be helpful in probing for the FID status or (or otherwise) of doubtful extracts. Those frames are (to support a PN – purely narratorial – or ID categorization):

I, the narrator, tell you, the reader [insert text to be probed, unmodified]

and, alternatively (to support categorization as FID):

[insert text to be probed, with any pronouns referring to the putatively discoursing character converted to first person, and with tenses converted to the present tense of thinking/speaking], **the character remarks, to himself or to other characters.**

Any sentence, or sentence part, can be put to these framing tests to help clarify their FID or PN status. But it has to be conceded that the shorter the fragment to be probed, the more difficult is this test to use; and FID does not invariably come in clause-size chunks. Still, to see how on longer fragments the test can be useful confirmation, consider these sentences from an early point in Gabriel’s final reverie in ‘The Dead’:

Perhaps she had not told him all the story.(1) His eyes moved to the chair over which she had thrown some of her clothes. ... (2) Poor Aunt Julia! She, too, would soon be a shade ... (3)

Taking these slightly out of order, the second of these sentences is clearly narratorial: although it fits the narratorial frame quite unexceptionally, it is clearly ludicrous if explicitly cast as characterological, via the second frame:

My eyes move to the chair over which she has thrown some of her clothes, the character remarks (to himself).

Conversely, sentence (3) is almost as incontestably characterological, FIT. Finally, the first sentence *Perhaps she had not told him all the story*, taken alone would seem to pass both the narratorial and characterological probe test: good evidence that, in theory, the sentence could be either narrator’s suggestion or character’s speculation. Again, context and cotext (and content: despite his rather protracted interrogation of her, it would be in Gabriel’s character to fear or suspect that not even Gretta had been entirely honest with him) make it overwhelmingly more appropriate to read this potentially ambiguous observation as Gabriel’s, in FIT.

As much as anything else, it is the modality in this last example – *Perhaps she had not told* etc. – and the expressive evaluation in the previous example – *Poor Aunt Julia! She, too*, etc. – that encourage us to assign FID interpretations. In seemingly narrative text, FID has the capacity to ‘put back’ all the immediacy and subjectivity and expressivity that otherwise, in standard ID, gets edited out. And this ‘restored’ subjective expressivity can extend to eccentricities of spelling and writing in general, reflecting the nonstandardness of the character: such features are comfortably accommodated in some kinds of FID. All of this amounts to a restoration of the colorful individuality of characters’ direct expression. We feel FID to be more vivid and colorful than PN and ID report because both the latter tend to be more detached, sober, restrained, and standard-English-speaking than the words of the character *in situ*, undergoing the experience and talking and thinking their way through that experience in frank and uninhibited ways. Of course the latter is an *effect* of direct experiential reaction, but no less significant for that.

As elsewhere in narrative study, it is the perception of difference (here between character speech and narrator speech) that is the true criterion. And in some narratives, as in the novels and stories of Henry James, where narrator and characters seem to share a single lect so that contrasts scarcely arise at lexicogrammatical levels at all, the differences can only be painstakingly derived from a reader’s assessment of protagonists and their discourse (e.g., its varying degrees of reasonableness).

FID: Functions and Effects

Perhaps no other feature of literary language has attracted as much attention from so broad a range of critics and linguists in the last 100 years as FID. Some have especially emphasized the ‘dual voice’ effect of FIS: notably in the work of Ullman, Pascal (1977), and McHale (1978), as well as in various of Bakhtin’s writings. Others, developing ideas in Benveniste and Hamburger, have dwelt on the ‘unspeakability’ of the FID sentence and of narrative sentences generally (especially Banfield, 1982). For Banfield, narration is unspeakable because, unlike discourse (which is both communicative and expressive), it is a text with neither a genuine addressee (nor any textual traces of one) nor a genuine expressivity-disclosing speaker. FID, in partial contrast, carries abundant expressivity (that of the character), but still no genuine I-you communicativity, and as a result remains unspeakable. Depending upon how the object of study – the novel, for example – is viewed, both or all of these seemingly disparate claims are

defensible and insightful. And it certainly seems likely that the ‘disappearance’ of the teller from heterodiegetic narratives, the bleaching out of the narrator as a felt presence in the text and denoted by prominent use of the first person singular pronoun and by evidentials, may have created the conditions in which free indirect effects could first emerge.

FID can be related to such fundamental literary distinctions of narrative method as those between showing and telling, or the neo-Platonist terms *mimesis* and *diegesis*. Mimesis presents ‘everything that happened’ as this might be perceived by a witness within the scene (thus a partial and far from comprehensive account). Stanzel (1981) noted that it typically comes with internal character focalization. Diegesis presents everything that a detached external reporter decides is worth telling – a reporter who is able to reflect, reorganize, and decide upon the point or teleology of the story prior to narrating it. In terms of mimesis and diegesis, FID amounts to a mimetic diegesis (a telling that shows or presents aspects of the character’s ‘own’ words or thoughts). In particular it is a showing that does not, by comparison with DD forms, draw so much attention to itself or to the fact that it is a showing. As a device for character portrayal by covert showing, FID can be related to a more thoroughgoing narrative strategy for showing character, known as Mind Style, in which the whole style of a passage or section seems to reflect the quality of someone’s mind – usually the mind of a focalizing character.

But there are numerous ways of characterizing FID, in fact, and these varied characterizations reflect the various functions that, in different circumstances, it can serve. It has been called substitutionary narration; combined discourse; ‘contaminated’ narrative, a tainting or coloring of the narrative; and dual voicing. Yet another approach is to view FID as a strategy of (usually temporary or discontinuous) alignment, in words, values, and perspective, of the narrator with a character. The idea of alignment does not prescribe whether that closeness of narrator to character is used for purposes of irony, empathy, as a vehicle for stream-of-consciousness or the clashing of two voices, or some other purpose.

Like McHale and others (Pascal, 1977; Ginsberg, 1982), Jefferson recognized that a key source of the impact of the FID sentence is its ambiguous mixture of proper narrative and proper speech or thought:

The dual voice of FID which is responsible for the superficially realist effect of immediacy is also an ambiguity which is highly unrealistic. From a realist point of view, FID is a doubly disconcerting use of language: its ambiguities cut it adrift from the two points at which we

commonly imagine language to be anchored to reality, the speaker and the referent. It is neither fully expressive nor fully referential, and this *invraisemblance* differentiates it most profoundly from other forms of reported discourse. (Jefferson, 1981: 42)

By *invraisemblance* Jefferson alludes in part to FID's lack of *vraisemblance*: the effect or convention of faithful and 'realistic' representation of the real world that many novels foster and many readers demand. The *invraisemblance* of FID stems from the fact that it gives rise to sentences such as *Perhaps she had not told him all the story*, and *She too would soon be a shade* and *Yes, the newspapers were right* which, in just those forms and with just those referential commitments, none of us in the discoursing of everyday lives, including our storytellings embedded in conversations, could ever actually say. FID sentences are in this sense unsayable or unspeakable, impossible to anchor to one speaker at one place and time, because they are impossibly divided between two distinct speakers (narrator and character) and anchorages. Following Bakhtin, critics have argued that in some of these cases the represented speech or thought is 'reaccented' by the representing narrator, so that two distinct accents, dialects, or intonations (which are never neutral, always evaluative) are held in a rich, unresolved tension. Certainly on some occasions, the clash of (character's and narrator's) sentiments within the FID passages is so palpable that a kind of internal conflict or mutual contradiction seems to be enacted.

Carefully handled FIT rendering can contribute to a subtle narrative presentation of characters' thoughts, in which the reader's awareness that a narrator is relaying those thoughts (even though narrator-oriented tense and pronoun choices are made) is thoroughly backgrounded. No matter how audacious or unreasonable the character's views become, no narratorial voice of 'true judgment' intrudes to censure the character or to dissociate itself from the character and *alert* the reader to the errors being broadcast. But actually FIT is often most powerful where the articulated ideas are *not* glaringly at odds with the narrator's assumed stance. Rather than by insulting or at least ignoring the reader's intelligence by imposing a narratorial gloss on the character's thoughts (there is no guarantee that the narrator is wiser, fairer, and more consistent than the characters, but that is the usual expectation), narration involving copious FIT – particularly when, as noted earlier, there is little reliably or blatantly to distinguish what the narrator might have reported in their own voice from what the character may have privately thought – may challenge the reader's intelligence and moral sensibility or

discernment. And in exercising that discernment we may have help only from juxtaposition: e.g., of one character's self-serving evaluations with actual outcomes or other characters' actions. Such effects are continually achieved in the novels of Henry James.

Finally, another indicator of the exceptionality of FID is the way that it often presents particular challenges to the translator. Translation of FIS and FIT passages creates all kinds of challenges – e.g., when expressing what might be rendered in English as *How she loathed him!* in a language such as Finnish, which has only one gender-neutral third-person singular personal pronoun, *hän*. Or it may be that the prohibitions on introduction of character-expressive features into a sentence with ID tense and deictic selections may be rather stricter in the target language than in the source language (or vice versa) creating further incommensurabilities.

'Beyond' IT: NRTA and NI

The work of Leech and Short (1981), and very recently Semino and Short (2004), has done much to develop a systematic typology of speech and thought (and latterly, writing) representation categories relevant to English. Most of the categories they propose are widely adopted, but the two 'most indirect' ones for thought representation, merit further comment (the counterpart ones for speech, NRSA and NV, were discussed earlier). They are NRTA and NI. NRTA denotes narrative report of thought acts, and is roughly parallel to Cohn's category of psychonarration, in which the heterodiegetic narrator remains in the foreground throughout, even adds some general observations not originating in the character ("as others [...] had done before him"). In NRTA, then, there is a highly indirect report of a character's or characters' thought, in which the content is noticeably summarized and cast in narratorial terms. Very often an NRTA sentence serves to introduce a passage of more character-expressive discourse. In the following example, an NRTA sentence (here in bold) is flanked by FIT ones:

She had consented to go away, to leave her home. Was that wise? **She tried to weigh each side of the question.** In her home anyway she had shelter and food; she had those whom she had known all her life about her. O course she had to work hard, both in the house and at business. (Joyce, 'Eveline', *Dubliners*)

The new internal narration (NI) category has been proposed for "reports of mental states and changes that involve cognitive and affective phenomena but that do not amount to specific thoughts" (Semino and Short, 2004: 132), that is, reports of mental activity that is even less a matter of inner speech

than NRTA instances. The examples include the following (which all need to be imagined in appropriate contexts):

*Jim envied Mr Mulvaney;
The phrase made me a little sad;
I couldn't get the image out of my head.*

That there is narrational activity of this kind, where a character's affective or evaluative response is conveyed in nonspecific terms, is widely accepted. But whether this amounts to *thought*-presentation, where 'thought' denotes 'the reported words or wording that we treat as having run through the character's or narrator's head', is more open to question. It is not claimed or assumed that the actual words *envy* or *sad* or *can't get the image* registered on the consciousness of the individuals here reported experiencing these emotions or reactions, any more than if the text reported *Jim pummeled Mr Mulvaney* it would imply that the word *pummel* crossed Jim's consciousness. For that reason, some analysts prefer to categorize such examples on the other side of a watershed setting apart thought representation from narration, i.e., on the narration side. These examples are then treated as more about narration, mental response narration perhaps, than thought presentation – as indeed the NI labeling partly recognizes. They are judged not to sit comfortably within the same grouping as DT, FIT, and IT (where NRTA is regarded as the outlier, or 'most indirect' category). Whatever classification is adopted, the recent study of Semino and Short suggests that NI-type narrations of mental reactions are by some way the most frequent means of thought presentation (presentation, not representation, is significantly their preferred term) in modern fiction, biography, and journalism. They therefore merit further analyses and appropriate classification on a comprehensive narrational scale that might encompass the whole range from discourse representation, through narrative report, description, and comment (Bonheim, 1984).

Conclusion

As a topic in narratology and literary linguistic analysis, speech and thought representation will continue to dwell on the different ways and effects of rendering direct speech in fiction and on the subtly changing ways that writers are finding to create mergers, blends, alignments, and clashes of voices and viewpoints within FID. The point is worth emphasizing that all six main speech and thought representation types (DS, IS, FIS; DT, IT, FIT) are effects as much as they are stable formats defined by essential criteria (DS is in the present tense of actual speech, but so too can narration be; it may or may not have

quotation marks, be set out on the printed page on a new line, with indentation, at each change of speaker, and so on). And in various ways just what is 'licensed' or acceptable in each of these mutually defined formats changes in step with larger changes in the status and function of literature, with changes of technology and living conditions, and especially in the face of the rivalry from alternative (and themselves changing) modes of cultural production and consumption, such as film, theater, and television. In short what is grammatical in each of these formats has shifted over time, and to some degree will continue to, and such shifts are both a cause and an effect of readers' changing literacy skills in this area – their adjusted ability to read and accept such a format as an effective rendering of a character's articulated thoughts, or of such thoughts interwoven with a narrator's distinct (and variably sympathetic or critical) viewpoint.

Spoken Discourse: Types

G Pianese, Naples, Italy

© 2006 Elsevier Ltd. All rights reserved.

Introduction

By definition, spoken discourse consists of at least two people taking turns who interact in an initiation and response structure (Sinclair and Coulthard, 1992). Some of the most typical features of spoken discourse are personal involvement and real-time constraints. Involvement is generally marked by using first and second personal pronouns; by monitoring the communication channel through rising intonation, pauses, requests for back-channel responses; by giving emphasis to people and their relationship; by reporting speakers' mental processes and by using emphatic particles (*really*, *just*, etc.). Real-time constraints, on the other hand, are highlighted by place and time adverbs, or by verb tense and aspect (Biber, 1986; Tannen, 1982). This description of spoken texts emphasizes the contrast with written texts, which may also be represented by the following oppositions: involvement vs. detachment; maximal use of context vs. maximal background information; inexplicitness vs. explicitness; dependence for effect of paralinguistic and nonverbal channel vs. dependence on lexicalization to establish cohesion; and so on (Tannen, 1982).

Spoken discourse features are not determined by contrast to written discourse features alone. As the range of variation of spoken texts is so great, from trivial conversation to elaborate political speeches, etc., reference is made to a typology of spoken discourse. Discourse types are characterized by different uses of linguistic structures, refer to specific social contexts and situations, to participants having specific roles and status, and are controlled by social rules and conventions.

The main problem with assigning type labels is whether discourse should be classified from

a structural or from a functional point of view. Researchers have questioned which of the two perspectives is more relevant in a typology of spoken discourse. On one hand, all utterances have a meaning, a purpose, or an intention (the functions of the utterances). On the other hand, the words in the utterance, the linguistic structure, determine its functions. More often than not, the only way to understand the function of the utterance is by referring to situation, discourse structure, and intonation, whereas the linguistic structure of the utterance is the least helpful in this respect.

The next section briefly explores these different approaches. Here, we will use *text* and *discourse* as synonyms. In fact, the two terms have a different background of uses in linguistic studies. According to Virtanen (1990: 447), "*text* is often used of a static concept – the product of a process – while *discourse* is used to refer to a dynamic notion – the process of text production and comprehension. It is the processual approach that naturally takes situational context into account."

Types of Spoken Discourse: A Review of Functional and Structural Approaches

Over the last few years, many studies have attempted to determine the nature and extent of structural and functional similarities and differences between spoken and written texts, in order to provide some theoretical and empirical prerequisites for comparative discourse research.

Traditionally, and according to rhetorical theory, four basic kinds of discourse exist: narration, description, exposition, and argumentation (De Beaugrande & Dressler, 1981; Werlich, 1983). These theories emphasize the functional aspects, and the different kinds of speaker contributions are considered prominent. Levelt (1989) states that one of the most important features in a typology of texts is the mutual agreement

that interlocutors have in the interaction. Levelt (1989: 111–112) affirms that it would be a problem if a speaker “constructs his messages in the framework of the wrong discourse type – for example, if he takes an examination to be a debate, or air-traffic-control discourse to be everyday conversation.” Discourse type is established by considering the way the talk is led; for instance if a person talks like a doctor (i.e., speaking of hematoma instead of a bruise) the interlocutor recognizes that the discourse is of the doctor–patient type.

Considering this, Levelt lists some of the different types of discourse as follows: informal everyday conversation, narrations, lectures, examinations and interviews, debates, planning discourse, route direction, radio talk, and therapeutic discourse. One of the main characteristics of informal everyday conversation is “the interlocutors’ awareness of informality, of roughly equal rights to the floor, and of the freedom to change topic” (Levelt, 1989: 111). One of the most remarkable differences between informal and formal discourse concerns the turn-taking rules to follow. Heritage (1998: 164) observes that in analyzing interactions one should immediately consider if they involve the use of a special turn-taking organization. In institutional interaction, we normally have a turn-taking organization and the types of contributions speakers are expected to make can be predictable. Consequently, departures from it can be explicitly sanctioned, such as “in meetings when speakers are ruled ‘out of order’, in the courts when persons are sanctioned for answering when they should not, or failing to answer appropriately, or when children in classrooms are punished for ‘shouting out’ answers, or talking when the teacher is talking” (Heritage, 1998: 165).

Informal everyday conversation is a label under which many other sublabels could be included. The range of informal everyday conversation is indeed very wide: from chatting with peers to chatting with parents or children, from male to female ways of chatting; from narrations to dialogues, etc. There are some considerable differences between male and female discourse. According to Tannen (1992), one of the greatest differences is the way they report facts: women complain that men tend to tell only the indispensable, whereas men complain that women give too much useless information (see also Carter *et al.*, 2003: 286–287). Tannen thinks this happens because men and women have different approaches to narrations: men see the recounting of incidents as a reporting, while women pay more attention to the metamessage because they feel that recounting experiences is a way to relate to the listener. Another

difference between male and female discourse is represented by what Kendall and Tannen (2001: 555) refer to as the taking up of roles of expertise or authority. Men tend to take up this role very often, while women are more likely to avoid it.

An important feature of narrations is interlocutor awareness of the following: “a single speaker has a preferential right to the floor until the narrative is completed. The speaker can count on the suspension of disruptive self-selection by other participants, but has to pay by having to generate a structured sequence of messages” (Levelt, 1989: 111).

A more formal type of discourse includes lectures, examinations, interviews, and debates. Levelt (1989: 112) defines lectures as more serious and impersonal, remarking that when lecturing the speaker is supposed to make his views known to a “spatially marked audience.” Examinations and interviews are instead “characterized by a fixed question-answer turn order, in which roles are clearly divided as to who does the questioning and who gives the answers” (Levelt, 1989: 112). Debates are considered to “share much of the question-answer nature of examinations, but the role of questioner is now equally distributed between the participants, and each participant has some thesis to defend” (Levelt, 1989: 112).

The informal vs. formal conversation opposition may also be referred to in terms of institutional vs. noninstitutional interaction. According to Heritage (1998: 164, 175), some features of institutional interaction are the asymmetries of participation and the involvement of the participants in specific goal orientations connected to their institutional identities: doctor and patient, teacher and pupil, etc. For example, in a medical setting, Tannen and Wallat (1993) observed information exchanges between a mother, a child, and a pediatrician. Results showed that the pediatrician used three different registers depending on the three different audiences. She switched from one code to another, using different intonation, voice quality, content, and lexical and syntactic structures. The register used when addressing colleagues and performing diagnostic procedures can be defined as reporting. It is characterized by flat intonation, rapid rate of speech, relatively low pitch, and the absence of marked facial expressions and gestures. However, when addressing the child the pediatrician used motherese, as in the following example:

Doctor: Let me look in your ear. Okay? Do you have a monkey in your ear?

Child: [laughing] No.

Doctor: No? ... Let's see ... I see ... a birdie. (Tannen and Wallat, 1993: 39)

Finally, she used everyday conversation register when addressing the mother:

Mother: It just appears that way?

Doctor: Yes. It's very ... it's really ... it's like floppy you know and that's why it sounds ... the way it is.

Mother: She worries me at night (Tannen and Wallat, 1993: 39).

Tannen and Wallat also noticed that the pediatrician suppressed her emotional responses and monitored the amounts and the impact of information imparted. Emotional response to a medical problem by a friend is quite appropriate, whereas a doctor's emotional response could cause the patient to panic.

Another way speakers adapt to institutional contexts is by selecting descriptive terms. For instance, one could use 'cop' in everyday conversation, but when giving evidence in court one would select 'police officer' instead (Sacks, 1979). In medicine, where references to pain are often euphemistic, a patient will be asked 'Is it sore?' instead of 'Is it painful?' (Heritage and Sorjonen, 1994: 174).

The typologies described so far give priority to functional rather than structural analysis: first functional characteristics are isolated, and only later linguistic features are identified on the basis of the predefined functional distinctions. As opposed to this methodology, Biber (1988: 13) noted that even if a set of texts have similar functions, texts may not necessarily have similar forms. On the contrary, if texts share similar linguistic features, they are also expected to have functional similarities, "because linguistic cooccurrence reflects shared function. The order analysis is reversed from previous studies, however. The types are first identified on the basis of their linguistic characteristics and only subsequently interpreted functionally" (Biber, 1989: 4). Biber (1995: 320) also remarked the salient difference between text types and registers, and highlighted the linguistic predominance in identifying text types. He noticed that text types are similar to registers in that they "both can be described with respect to their linguistic characteristics and with respect to their situational/functional characteristics. However, these two constructs differ in their primary bases: registers are defined in terms of situational/functional characteristics, while text types are defined linguistically."

Biber's new approach to identifying text types is based on sets of syntactic and lexical features that frequently co-occur in texts. He calls these feature sets, empirically identified dimensions of variation, and the linguistic characteristics of any given text can be specified precisely with respect to each dimension. The dimensions and associated text characterizations provide the basis for his typology. According

to Biber (1989: 7), there are 16 main grammatical categories that the linguistic features fall into:

(A) tense and aspect markers, (B) place and time adverbial, (C) pronouns and pro-verbs, (D) questions, (E) nominal forms, (F) passives, (G) stative forms, (H) subordination features, (I) prepositional phrase, adjectives, and adverbs (J) lexical specificity, (K) lexical classes, (L) modals, (M) specialized verb classes, (N) reduced forms and dispreferred structures, (O) coordination, and (P) negation.

After preliminary analysis, he identifies a five-dimension system to represent communicative functions, in order to deal with all text types (e.g., face-to-face, telephone and public conversation, debates, interviews, broadcast, spontaneous speech, and planned speech). The five dimensions are labelled as follows (Biber, 1989: 10):

1. Involved vs. informational production
2. Narrative versus non-narrative concerns
3. Elaborated vs. situation-dependent reference
4. Overt expression of persuasion
5. Abstract vs. nonabstract style.

Biber uses quantitative techniques to identify the groups of features that co-occur in texts, and then groupings are interpreted in functional terms. However, Biber (1989: 41) underlines the continuous range of variation among texts and the different score the text may have on each dimension, in a continuous, multi-dimensional space of variation.

In order to handle this lack of balance between linguistic structure and function, Sinclair and Coulthard (1992) developed a model for spoken discourse analysis, using Austin's speech act theory and Halliday's description of grammar based on a rank scale (they were inspired by Halliday [1961]. Their model first appeared in Sinclair and Coulthard [1975], *Towards an analysis of discourse: the English used by teachers and pupils*, and then in Sinclair and Coulthard [1992]). Sinclair and Coulthard aimed at making a practical and functional description of discourse. They began with classroom settings because of their simple interaction patterns, and similar discourse rules with other situations, thus creating a system suitable for all discourse analysis. Sinclair and Coulthard observed that in classrooms, the teacher initiated (I) all exchanges, the students responded (R), and the teacher would follow up (F) on what had been said or done, creating an I-R-F type of discourse. This system is useful as it focuses on the speaker tactics used to determine the purpose of utterances. Sinclair and Coulthard define lessons as the greatest unit of classroom discourse, consisting of several transactions marked off by the boundary elements,

the 'frame': *right, well, good, OK, now*. These terms are frequently used by all teachers, and mark the end of one stage and the beginning of the next. The function of the 'focus' (a special kind of statement) in the transaction is to tell the class what is going to happen; and they generally occur after frames. Sinclair and Coulthard are aware that the order of transactions varies for each teacher and there is no restriction on the occurrence of different types.

Types have no defined boundaries; on the contrary, they are characterized by a continuous range of variation, which can be grasped only when observing concrete data. It is impossible to label types without data. Theoretical findings do not always reflect what in effect happens in practice. For example, Basturkmen (2003: 21–22) has investigated the ways the presence and absence of the tutor impacted on the exchange structure of an academic discussion. In contrast to his expectations, his analysis did not show that the authority figure dominated by controlling the interaction, i.e., by initiating exchanges; on the contrary, during interaction in presence of the tutor, half the exchanges were initiated by students. He also observed that the arrival of the tutor made the discussion become more solution-driven rather than idea focused, with a large number of student–student exchanges.

A further example of spoken discourse is sports broadcasting. According to Ferguson (1983), sports broadcasting shows a particular use of syntax and register. He considers it as a discourse genre and analyzes it in terms of register variation. The register is located by the characterization of its occasions of use – such broadcasts start with background information about the game, the occasion, the teams, and so forth; they include components of direct reportage, comment, advertising commercials, and conclude with interviews of players and coaches. These elements are in relatively fixed proportions and relatively fixed sequence, and selected syntactic characteristics are also identified such as simplification (deletion of copula and sentence initial nominals, which give both the lowering of pitch and loudness for parenthetical expressions and structural simplification), inversions (“Holding up at third is Murphy”; Ferguson, 1983: 160), heavy modifiers (“Eddie Yost, a *crackerjack*, who was not a *power hitter*, ...”; Ferguson, 1983: 163), result expressions (*for + noun* “He throws *for the out*”; *to + phrase* “And he just keeps alive, reaching out *to foul-tip one back*”; Ferguson, 1983: 161), routines (e.g., giving the count: “One and one”; Ferguson, 1983: 166).

Conclusion

The list of types of spoken discourse taken into account here is in no way complete. Instead, our aim

was to emphasize some critical points related to the problem of establishing the typology of spoken discourse, such as the limits and the indistinct boundary of all kinds of typology, and finally the priority of the functional or structural perspective.

Rather than trying to encourage a tolerant attitude conciliating both approaches, or to establish priorities between them, the old chicken and egg problem remains: how to decide which comes first? “The situation we’re in (e.g., a committee meeting)? Or the language we use (our committee ways of talking and interacting)?” (Gee, 2003: 11). According to Gee, this reciprocal process through time is just the core of the magic property of language: “when we speak or write we craft what we have to say to *fit* the situation or context in which we are communicating. But, at the same time, how we speak or write *creates* that very situation or context” (Gee, 2003: 11).

Stylistics

K Wales, University of Leeds, Leeds, UK

© 2006 Elsevier Ltd. All rights reserved.

Definition and Domain

Stylistics is broadly and simply 'the study of style,' a concept that is widely known and used, but that is difficult to define and has many different shadings. What is certain, however, is that its essence is 'distinction,' 'variation,' or 'choice': in any language there is always more than one way of writing or speaking the same (sic) message, but with a different connotation or effect as a result. Stylistics as a discipline takes as its base this essential variation, whether at the level of phonology, grammar, lexis, semantics, or discourse. It differs from sociolinguistics, where style is seen as a variable within a continuously evolving sociolinguistic system, in being concerned with the functional significance of style. It characteristically deals with the interpretation of texts by focusing in detail on relevant distinctive linguistic features, patterns, structures, or levels and on their significance and effects on readers. It presupposes that every linguistic feature in a text has potential significance. It draws its terminology and models from various appropriate branches of linguistics, and one of the commonest collocations and metaphors associated with it is 'toolbox' or 'tool kit.' Since attention is predominantly text centered,

stylistics could arguably be a branch of text linguistics; and since it uses linguistic frameworks, it could also be seen as a branch of applied linguistics. It is sometimes also called *literary stylistics* or *literary linguistics* (see, e.g., Fabb, 1997; Stockwell, 2000) because the most common kinds of texts traditionally analyzed have been literary. It could also be regarded as a branch of poetics, which is primarily concerned with the classification of the essential properties or conventions of genres, or theories of form. There is some overlap in usage, however, and in territory: there are stylistic studies of satire, parody, and humor, for instance.

Nonliterary discourse and varieties or registers are well within the scope of general stylistics or sociostylistics, and spoken as well as written; increasingly attention is being drawn cross-modally to media discourses such as those of film, news reporting, advertising, politics, and hypertexts and to the oral discourses of storytelling and song lyric. The term *linguistic stylistics* is sometimes found, which acknowledges the fact that some stylistic studies are as interested in providing insights into the workings of language and in testing the validity of linguistic models as they are in providing insights into how texts mean. However, it has to be said that a stylistic study of any merit will say as much about (the limitations of) the model as about the text under scrutiny.

Roger Fowler's term for stylistics was *linguistic criticism* (1986), reflecting not only the fact that primacy is assigned to language, but also that the goal of stylistic studies is not simply a mechanistic description of the formal features of texts for their own sake, whether phonological, grammatical, or lexical – a common myth about the early years of stylistics in Britain in the 1960s. Linguistic analysis, however objective or empirical, is no substitute for deductions and judgments. The aim is to find linguistic evidence for a critical judgment; to ground intuitions or hypotheses in a rigorous, methodical, and explicit textual basis; to produce an analysis that is verifiable. Fowler's term, *linguistic criticism*, also implicates stylistics with literary criticism and practical criticism, with their own focus on relating analysis to textual interpretation, but usually more broadly. A related term to Fowler's is *practical stylistics* (see Widdowson, 1992). Both literary criticism and stylistics can thus be seen as subdisciplines of hermeneutics, but stylistics is as much focused on *how* texts mean, as on *what* they mean, even though the goal may well be a specific literary-critical reading. Unlike literary critics, however, stylisticians must be concerned with language, and stylistics provides a metalanguage for principled and systematic discussion of it, in its concern also to avoid subjective or impressionistic judgments based on unverifiable intuitions. (Not that good literary criticism is vague or impressionistic).

Stylistics in Britain at least has tended to fight shy of evaluation, of what is good or bad style, possibly as a reaction against the prescriptivist Leavisite tradition of literary criticism and notions of the canon. Assessments are indeed made, but of the effectiveness or appropriateness of specific stylistic features to their perceived function or contribution to the totality of interpretation. Stylisticians have to be wary, however, of making oversimplistic iconic equations between language forms and functions or meanings (the so-called enactment fallacy), despite the characteristic symbiosis in poetry in particular between form and meaning. For, as Simpson rightly argues (2004: 2), linguistic features 'do not of themselves constitute a text's meaning', but act as a 'gateway' to its interpretation. It therefore follows that more than one interpretation is possible. In recent years it has certainly been the case that stylistics has developed a harder edge and engaged in critique. For example, many stylistic studies draw their frames of reference from critical theory (e.g., postcolonialism and the writings of Foucault on *discours*) and feminist stylistics is an important subbranch (see Mills, 1995). This has exposed areas of bias, inequality, and subjectivity where ethical issues can be raised. Very significantly, as a

result of Roger Fowler's interest from the 1980s onward in critical linguistics, stylistics began to place emphasis on language and texts located and functioning in particular social, ideological, and political practices and has exposed linguistic ambiguity and obfuscation. So it has come increasingly to overlap with the Faircloughian critical discourse analysis (CDA), by which it has also been much influenced. But stylistics has always stressed the inseparability of form and content, which underpins the CDA approach, and the impossibility of a neutral or unmarked style. Deidre Burton's piece (1982) on the grammatical choices in Sylvia Plath's *The Bell Jar* could indeed be seen as a forerunner of CDA, in its argument for a radical stylistics that actually effects social change. In turn, CDA tends to use the 'tool kit' approach of stylistics as part of its methodology.

Stylistics in Academia

Because of its interface with many other different kinds of disciplines, stylistics tends to find itself both marginalized and appropriated at one and the same time in higher education in the United Kingdom. Stylisticians have tended to find themselves caught between a literature and linguistic divide that has been slow in narrowing. At the end of the 1970s the Poetics and Linguistics Association (PALA) was founded by a group of like-minded scholars (including Ronald Carter, Roger Fowler, Mick Short, and Katie Wales) to provide a common forum and to legitimize stylistics as a professional discipline. The name of the association was chosen to reflect Roman Jakobson's famous statement that "a linguist deaf to the poetic functions of language and a literary scholar indifferent to linguistics are equally flagrant anachronisms." By the end of the 20th century, PALA had grown worldwide, with an annual conference and its own international journal, *Language and Literature*, which produces an annual resume of the year's work in stylistics.

As a branch of applied linguistics, stylistics even today may or may not be studied in the United Kingdom as part of a linguistics degree; with an emphasis on literature, it may or may not be part of an English or modern languages degree, although increasingly it features as a component of courses introducing students to critical theories and practices for text analysis and most recently as a component of creative writing courses. In the future this will undoubtedly mean that more attention will be paid to the pragmatic evaluation of style and the rhetoric of composition. Stylistics is increasingly studied as part of an

English language degree, because of its popularity with English-speaking linguists researching aspects of English language, both synchronically and diachronically. English language degrees are themselves now flourishing as a result of the increased attention paid to English language studies in the last decades of the 20th century at the advanced level, and stylistics has accordingly found itself a receptive audience among secondary-level teachers and students of both language and literature.

The attraction of stylistics in the pedagogic context, namely that it combines a knowledge of the principles of language and usage with a critical interest in the interpretation of texts, has long been known outside the United Kingdom, in institutions and courses from Europe to Japan (e.g., those run by the British Council) where the language and literature of second languages, English in particular, are taught. The argument of those involved in pedagogical stylistics is that it enables students to be more aware of, and to be more explicit about, language features and use and at all levels of phonology, graphology, grammar, lexis, meaning, and discourse by providing them with an appropriate framework and vocabulary: the 'tool-kit.' It also helps students to be more independent in their judgments, by forming their own interpretations of literary texts based on close readings and to be more confident in articulating them. Some teachers believe that stylistics helps students to improve their own writing skills, as well as their reading skills, but empirical evidence for this is hard to find. The stylistics approach has always been very accessible, practical, and interactive, and publications in this area have focused on teaching materials (see, e.g., McRae, 1998; Widdowson, 1992). Rewriting exercises of the kind practiced in pedagogical stylistics (e.g., from prose to verse, changing perspective or focalization) have refreshingly found their way into United Kingdom textbooks like Rob Pope's (1995). With the increasing interest in English in China in recent decades, stylistics has become a major discipline; here as elsewhere, it has proved a staple of translation studies in both ancient and modern languages as well as English (see further Shen, 1995).

A Brief History of Stylistics

Already it can be seen that stylistics continually over-spreads any firm discipline boundary because of its engagement with other related disciplines across the arts, humanities, and even social sciences. Historically this has resulted in what can be termed a paradigm

shift, although many concepts and strategies remain central or are continually being reassessed or even revived.

It is difficult to pinpoint the exact beginning of stylistics, because of its probable multinational origins at different times. One major root lies in the earlier study of *elocutio* in Western and European rhetoric, concerned with stylistic devices and patterned language such as schemes and tropes, which still plays a significant part in the teaching of composition in higher education in the United States. Other aspects of rhetoric remain of significance (e.g., its concern with the skills of public speaking as a means of persuasion, as having an effect on the audience). A general interest in rhetoric has recently been revived from a cognitive stylistics perspective (see further later discussion). The term *stylistique* was introduced by Charles Bally (1909), a pupil of Ferdinand de Saussure, and interest spread across Europe aided by the work of Leo Spitzer in particular (1928, 1948). Spitzer's interest tended to be writer centered: style seen as revealing the soul of the writer, and with an aim to find the creative principle of the text (expressive stylistics). His concept of the *philological circle* has been more enduring and is characteristic of the stylistician's procedure still today: constantly and delicately moving between hypothesis, linguistic analysis of data, and critical explanation and aesthetic response, with a revised hypothesis if necessary. Later continental stylistics in France aligned itself with semiotics, narratology, and philosophy; in Germany it acquired a diachronic and nonliterary emphasis. (For useful summaries of preoccupations in present-day *Stilistik* in Germany, see Sowinski, 1999; for *la stylistique* in France, see Molinié, 1997.)

In the 1960s stylistics took hold in Britain and the United States, given impetus from developments in descriptive linguistics, particularly grammar. The United States led the way in international journals of stylistics, notably *Language and Style* and *Style*. Michael Halliday proved a key figure in Britain (and subsequently Australia), first of all with his scale and category grammar, and also his concept of register as a situational use of language. But it is his later systemic-functional model of grammar that persistently provides one of the most popular tools in stylistic analysis, because of its comprehensive set of lexico-grammatical categories that label mental processes, verbal and material actions and so are able to tackle full-length naturalistic texts more easily than a generative grammar. His idea of *transitivity* in particular also underpins many writings in feminist stylistics and CDA.

Early stylistic studies of the 1960s in Britain and the United States were much influenced by the newly discovered early 20th-century works of the Russian Formalists, the Prague School, and the writings on poetic language and meter by Roman Jakobson; and terms like *parallelism*, *norm*, *deviation*, and *foregrounding* entered the stylisticians' vocabulary (see van Peer, 1986 for the latter): concepts and terms recently revived with a cognitive slant by Cook (1994). Leech (1969) happily blended Formalism and *elocutio* in his schematic reassessment of patterned language and metaphor in poetry. There was certainly a tendency in the early days of stylistics, later corrected, to study poetic texts, particularly those showing a high degree of linguistic creativity or experimentation. Jakobson's notion of literariness was much debated and still is, although stylisticians today tend to agree with literary critics in seeing a continuum of literariness in language across nonliterary as well as literary discourses (whether high or noncanonical). They tend to argue also that cultural expectations about what makes a text literary are as highly significant as prototypical linguistic, metrical, and textual features. Nonetheless, there are those who would argue, in line with Jakobson's emphasis, that literary texts have a different social function from nonliterary texts (see Widdowson, 1975, 1992; Verdonk, 2002); and it is certainly the case that aesthetic uses of language remain of central interest in stylistics, and studies of poetic form and prosody provide a flourishing subbranch of the discipline.

At around the same time there was also a brief flirtation with generative grammar as a model, because of its then interest, for example, in deviation, by the violation of selection rules or by degrees of grammaticalness, particularly in modern poetic texts such as those by e. e. cummings. The inheritance of generative grammar, however, as indeed of Formalism, proved more robust in generative metrics and in later evolved studies of metrical form (see, e.g., Fabb, 1997).

From the outset in Britain stylistics tended not to be writer centered. Although concerned with the concept of *narrator*, it showed little interest in authorial intention, as in traditional literary criticism. Periodically, however, there has been interest in stylistic features that mark an author's *idiolect* or voice print across an oeuvre or in changes of style between early and later works or that indicate provenance, especially in computational stylistics and forensic stylistics, where cases of disputed authorship arise. There has also been an implicit awareness that any choice or selection of stylistic features must have been the author's. The concern in the 1960s and early

1970s was very much with the reification of the text as an artifact (formalist stylistics). One inheritance of this is the implicit assumption that the text under scrutiny is coherent and cohesive.

However, with the development in the 1970s of disciplines such as discourse analysis and pragmatics in linguistics on the one hand and reception aesthetics and reader-response criticism in literary theory on the other, stylistics shifted its focus to the text in its interactive discourse context (functional stylistics, discourse stylistics, or contextualized stylistics) and to the reader as constructing the meaning of the text, rather than as simply the decoder of a given message or single or eternal truth encoded by the writer. There was a more explicit recognition that the parameters of the situational context contributed to a text's meaning, and that therefore contextualization needs to be part of the theory or model. The writings of the Russian linguist-philosopher Mikhail Bakhtin, newly discovered and translated in the West, gave a refreshing boost in the 1980s to the study of the style and structure of prose fiction in a sociostylistic context and introduced the notion of *intertextuality*, texts and their voices in a creative dialogue with others. Prose fiction inevitably lent itself to macrodiscourse approaches, such as *focalization* or *point of view* and *speech and thought presentation* (see Leech and Short, 1981), which continue today, aided by the advent of corpora for empirical testing and verification. However, stylisticians are still firmly committed to linking macrostructures to the micro, specific linguistic features, themselves. Burton (1980) led the way in the stylistic analysis of drama by applying a comprehensive discourse model matching fictive dialogues against real-life conversational practices. This was later followed in many studies by the application of pragmatic models of politeness and speech act theory. Herman (1995) remains the most comprehensive analysis of drama from different perspectives, recognizing that drama's discourse context is characteristically complex.

Certainly, in general, the awareness of context meant that a diachronic stylistics could valuably develop, matching trends in pragmatics, with a sensitivity to nuances of style and significance in texts grounded in a sociohistorical, rather than simply in an ahistorical context; and taking into account differences of reader or audience expectations from earlier periods (see, e.g., Adamson, 2000). A diachronic stylistics also looks at the historical development of significant stylistic devices, such as free indirect speech and thought. The increasing awareness in pragmatics also of the need to embrace a cross-cultural perspective, for example in politeness theory,

is influencing many studies in contrastive rhetoric, especially those embedded in English as a Foreign Language pedagogy and also drawing inspiration from the field of genre analysis.

Current Trends in Stylistics—and the Future?

Stylistics today is still broadly concerned with the creative negotiation of meaning and affect between texts, contexts, and readers, and this emphasis has been reinforced by developments not only in pragmatics, but also in cognitive linguistics. The 1990s saw an emerging interest in the application of relevance theory (relevance stylistics): phenomena such as poetic metaphors leading to extra interpretive effort on the part of the reader. In what is called cognitive stylistics, or cognitive poetics more generally, there is a strong interest in the actual reading process (rather than the end product) and how specific linguistic features or textual elements trigger a reader's understanding and the mental creation of the world of the text, especially in fiction (see Emmott, 1997; Werth, 1999); also in the understanding and processing of metaphors and the manipulation of prior mental schemas and frames of knowledge (see Semino and Culpeper, 2002). As with other strands of stylistics, the most interesting research tests the strength of the cognitive models much as illuminating the text under discussion. Cognitive linguistics in general breaks down the traditional binary opposition between *literal* and *figurative* meaning, which is appealing to stylisticians. In its history it has contested many such oppositions, inherited from the worldview of a Saussurian structuralism (e.g., *text* vs. *context*; *literary* vs. *nonliterary*; *mimesis* vs. *diegesis*).

Although a focus on process is to be welcomed, for the future, however, stylistics must continue to concern itself as much with the social, cultural, and historical contexts as the cognitive and take more notice of global discourse communities, rather than Anglocentric, in which texts are constructed and construed, and to the diverse nature of real readers and reading publics. Recent work at the University of Nottingham on spoken corpora under the direction of Ronald Carter has highlighted the creativity of ordinary speech, but there is also still a great need for the stylistic analysis of computer-enhanced large-scale corpora of a range of text and discourse types and from different periods and also for a stylistic perspective on lexical phenomena such as collocations and formulas in such corpora: all under the heading of a corpus stylistics. The new aesthetic multimodal genres of video games and Internet literature

also await more attention. Literary theorists have long prophesied the replacement of the study of literature by cultural studies. Stylistics is well placed to move into the analysis of forms of cultural production other than written texts.

Conclusion

As this account of stylistics illustrates, Lecerle (1993) is right to state, on the one hand, that no one has probably ever known exactly what the term *stylistics* comprises, yet, on the other hand, that the discipline is forever being reborn. Those engaged in stylistics see this as a strength, as in other disciplines that continually reassess their models and theories, and they embrace its eclecticism with zeal. That there is no one way to do stylistics might be disconcerting to some. However, stylistics is no different from many other disciplines at the present day in that there is continual cross-fertilization of ideas across subject boundaries and the stretching of its own boundaries at the same time. And although models may change or vary, the fact remains that those stylistic studies that are the most illuminating provide scrupulous insights into both the workings of language and the interpretations of texts that remain plausible and convincing to new generations of readers.

Stylistics: Pragmatic Approaches

Introduction

Pragmatics is typically defined in contrast with semantics. While both semantics and pragmatics are concerned with meaning, semantics deals with abstract and relatively stable meanings within the linguistic system, and pragmatics concerns itself with variable aspects of meaning which are derivable from utterances within contexts of use. As such, pragmatics can be, and often is interpreted, as covering a wide range of contextual factors, including, for some researchers, aspects of sociolinguistics, conversational turn-taking and narrative structure (see Traugott and Pratt, 1980), and cognitive poetics (see Radwańska-Williams and Hiraga, 1995).

Mainstream pragmatics; however, tends to focus on one or more of four models of language in use: Grice's cooperative principle and conversational maxims, Austin's speech act theory, Brown and Levinson's politeness principle, and Sperber and Wilson's relevance theory. These models are all originally developed with reference to nonliterary uses of language. In literary stylistics, pragmatic approaches fall broadly into two areas. First, there are those that take a general contextualized approach to understanding the reading of literary texts. These approaches overlap

to some extent with reader response theories, and are outlined in the section on wider literary reading contexts below. Second, there are those that use the particular pragmatic models mentioned above and apply them to literary texts, sometimes innovating on the complexities of problem solving and developing the models themselves, in order to account for literary communicative processes. Within this second area, there is a further distinction to be made between work that applies the pragmatic models to examples of communicative interaction between fictional participants in literary texts, and work that addresses the nature of the interaction between writer and reader. Some work addresses both of these communicative situations, and indeed views the complexity of embedded interactions as characteristic of the literary text. Examples of the application of specific pragmatic models are outlined here in the sections on speech act theory, Grice's pragmatics, and politeness. The stylistic applications of relevance theory are discussed in a separate entry, and so are not considered here.

Speech Act Theory

In speech act theory, an utterance is defined as an illocutionary act with recognizable syntactic form. In addition, the utterance has a locutionary force relating to the intention of the speaker, and an effect on the hearer. Speech acts, according to the theory,

fall into various categories such as representatives (i.e., stating what is believed to be a fact), verdictives (evaluating an event or situation), commissives (i.e., promising), declarations (bringing about a state of affairs, i.e., marrying). At different stages of its development, the theory has posited different sets of categories; and those given here are just a few examples. An important difference between types of speech acts is that some are truth conditional, and others simply have appropriateness conditions (also known as felicity conditions). Representatives are typically truth conditional in that the speaker is committing to the truth of his/her assertion, while declarations depend for their success on certain contextual factors; the declaration, 'I now pronounce you man and wife' is only valid if uttered in culturally appropriate circumstances by a person invested with the authority to marry.

In various pragmatic accounts of literature, a central concern is to define literature as what seems to be a rather a peculiar type of speech act; fiction appears to make assertions, but clearly without truth conditions. Austin himself claimed that his theory did not apply to "non-serious uses of language" such as poetry (see Levin, 1976). This view was elaborated by Searle (1979; see also Genette, 1990) and provoked a heated debate with deconstructionist critical theorists, who saw his characterization of literature as 'parasitic' upon the 'normal' use of language as a fundamental theoretical flaw (see Derrida, 1988; Rabinowitz, 1995). Others have taken a more constructive view, arguing that speech act theory can be developed in relation to literary communication.

Van Dijk (1976) does this by introducing the notion of speaker-hearer possible worlds, or S-worlds, which are relative, in terms of their truth conditions, to the individual speaker or hearer. The illocutionary force of the speaker is thus to change the S-world(s) of the hearer, but in literature there is a range of possible interpretations from which the hearer chooses the one that best matches his/her S-worlds. Literary speech acts, in van Dijk's view, do not function as acts whose intended outcomes are practical changes, but simply give access to the writer's S-worlds in the same way as saying how you feel or telling a joke might result in shared feelings and evaluations.

Levin (1976) discusses Ohmann's (1971, 1973) notion that literary utterances are mimetic of non-literary utterances, allowing the reader to construct a fictional situation that to some degree resembles his/her experience of reality. Levin, clearly influenced by generative grammar, goes further than Ohmann in proposing a higher-level implicit sentence in the deep structure of poems that announces its overarching illocutionary force of constructing a fictional world.

The deep structure of the first line of Yeats's poem *Byzantium* is, for Levin, '[I imagine myself in and invite you to conceive a world in which I ask you] What shall I do with this absurdity?' with the words in parentheses omitted in the surface structure of the poem. Levin also suggests that literary features such as meter, rhyme, assonance, etc., in the poetic locutionary act signal the unusual nature of its illocutionary force.

Traugott and Pratt (1980) also take a speech act approach to the literary text, based in part on Pratt's earlier book (Pratt, 1977), giving an overview of work in this area, and like Levin and Ohmann, arguing that literary speech acts are mimetic of non-literary speech acts. They offer several possibilities for the illocutionary force of the literary speech act, such as the intention to give pleasure, to establish shared understanding and values, to teach, and conclude by suggesting that literature allows for many communicative functions. Further detail of the aspects of their approach based in Pratt's earlier work is given in the following section.

Grice's Pragmatics

The aspects of Grice's theory relevant to this discussion concern his model of conversational interaction as dependent upon a cooperative principle along with four conversational maxims. According to this model, speakers and hearers in successful conversational exchanges engage in cooperative behavior that is manifested by adhering to, and trusting that the other participant is adhering to the maxims of quality, quantity, relation, and manner. The maxim of quality requires that a speaker should assert only what she or he believes to be true. The maxim of quantity involves giving just the right amount of information for the purpose of the utterance, neither too much nor too little. The maxim of relation requires us to use appropriate utterances relevant to the preceding discourse, and the maxim of manner requires us to give separate pieces of information in a clear and helpful order. Of course, people do not always behave cooperatively in conversations, and according to Grice, the cooperative principle breaks down when participants fail to adhere to, or violate the maxims. Violating the maxim of quality, for example, results in lying. Even when the cooperative principle is upheld, the maxims can be flouted for particular effects. Metaphor and irony, for example, are said to flout the maxim of quality, giving rise to certain implicatures (implications discernibly intended by the speaker).

Pratt (1977), also summarized in Traugott and Pratt (1980), suggests that in the literary text, the

cooperative principle is relaxed, and that this relaxation is enabled by the use of fictional characters and implied narrators (distinct from authors) as speakers. Referring to the third and fourth sentence of *Tristram Shandy*, Pratt reveals that Shandy's utterances violate all four of the maxims in numerous ways, implicating the author's intention to amuse the reader by enacting the ramblings of an uncooperative speaker. In another example, Pratt discusses Benjy, the retarded narrator of *The sound and the fury*, describing a game of golf in barely recognizable terms. Benjy's narrative fails to give enough information, and lacks indication of causal relationships between events. Pratt reads this as leading to an implicature on the part of Faulkner to the effect that Benjy's (or such people's) perspective is interesting because it is so different from our own.

Politeness

Brown and Levinson's (1987) model of politeness was developed to complement Grice's pragmatics, and to account for utterances which appear to violate the cooperative principle although participants still appear to be engaged in cooperative behavior. Some violations of the maxim of quality, for example, involve lying to avoid being rude to a hearer, and indirect requests similarly seem to violate the maxim of manner in order to avoid causing offence with a more direct equivalent. In this model, Brown and Levinson invoke the notions of positive and negative face. In polite exchanges, participants attend to positive face needs by attempting to meet one another's desires, and attend to negative face needs by not impeding or imposing on these desires. Departures from the conventions of the politeness principle involve what are termed face-threatening acts. Just as adhering to the politeness principle might involve violating the cooperative principle, performing a face-threatening act might conform to the cooperative principle. The two principles might operate in tandem, but will often require different verbal behaviors.

Simpson (1989) makes use of the cooperative principle in an analysis of Ionesco's play *The lesson*. His argument is less to do with what Ionesco might be communicating through the use of stage characters than with the use of politeness strategies as indicators of character construction and development. He discusses the interaction between two characters, a professor and his pupil, who meet for the first time early in the play. Tracing their conversations through the acts, Simpson shows that the professor begins as a diffident character and gradually becomes dominant in the relationship, while the pupil, who makes a confident start, becomes passive. These changes are signaled primarily through their linguistic exchanges;

the professor, for example, hedges and apologizes at the beginning of the relationship, but by the end is performing 'bald on record' face-threatening acts.

Leech (1992) takes a similar approach, using politeness theory in an analysis of Shaw's play, *You never can tell*, focusing in particular on the conflicting requirements of the cooperative and politeness principles, and examining the characters' attempts to resolve these conflicts in various ways, often to comic effect. Other uses of politeness theory in analyses of literary texts include works of Sell (1991b), Herman (1995), Kopytko (1995), and Lafuente Millán (2000).

Wider Literary Reading Contexts

Other pragmatic approaches address wider questions about the literary text and the literary reading process, making less use of the traditional pragmatic models, but still insisting on an attention to context and literary function as necessary to any explanation of literature. In several of these approaches explicit reference is made to literary pragmatics as a discipline that seeks to restore the significance of context in literary linguistics, and the consideration of works of literature as communicative acts, following the decontextualizing trends of New Criticism and the antiintentionalist ethos of late 20th-century critical theory, (see Sell, 1991a; Engler, 1991; McGann, 1991); Engler (1991), for example, rejects what he sees as one type of pragmatic approach to texts, which assumes determinate readings and commonality of readers' experiences, and privileges authorial intention, but he also rejects literary theoretical notions of interpretive communities (Fish, 1980) determining the direction of interpretation, arguing instead for a focus on the 'collaborative nature of textuality.' Lecercle (1999) sees the literary reading process as one that self-consciously raises questions about interpretation, arguing that reading itself is a kind of pragmatics.

How Literary Texts Work

Much of contemporary literary pragmatics is concerned to define literature as having a special functional and communicative status, yet at the same time operating on principles recognizably similar to those of nonliterary discourses. In this sense, a range of broadly pragmatic work approaches the literary text with the same questions as the speech act theorists of literature discussed earlier, but without recourse to the speech act model.

Van Peer (1991) introduces the notion of the homiletical texts and discourse, which occur outside of institutional situations. Literature, in van Peer's view, along with other texts and discourses,

is homiletical, and is therefore functionally vague. Homiletical texts generally have one or two of three characteristics: they are reflective, socially cohesive, or entertaining. Literary texts can be defined as having all three of these characteristics, and this combination, along with its homiletical status is what makes literature unique.

Generic conventions are pragmaticized in Chapman and Routledge (1999) by using the idea that readers entertain a set of presuppositions in approaching different types of fiction; for example, detective fiction. Just as in other nonfictional types of discourse, presuppositions can fail. Presupposition failure in a conversation between friends might lead to communicative problems, and will probably violate truth conditions; 'My dog needs a walk,' existentially presupposes that I have a dog, and violates truth conditions if I do not. In literature, on the other hand, Chapman and Routledge argue there is 'greater pragmatic flexibility,' allowing for generic deviations from normative sets of presuppositions for communicative effect. Paul Auster's postmodern novel *City of glass* is said to do this in various ways; for example, in manipulating narrative point of view, blurring the distinction between narrator and author and thus problematizing the notion of identity in a manner that would not be possible in nonliterary discourse.

What Literary Readers Do

The other side of the contextual question involves the role of the reader and the act of interpretation. Most work in this area challenges the notion that a text is simply a set of linguistic structures available to any reader able to decode them, and explores interpretive variability and the contextual factors influencing individual interpretations.

An example of this approach is Verdonk (1991), where the concern is with poetry as an act of communication that cannot only be determined by its form. The contexts relevant in a reading of a poem include, for Verdonk, the broad cultural environment of its reading, and the reader's knowledge of literary conventions and literary form. Formal features of literary language such as parallelism and deviation are said here to trigger pragmatic processing, but the direction of this processing will be determined by its context. For a more specific and localized account of the relationship between linguistic form and interpretation, see Alonso's (1995) analysis of responses to a short story by Katherine Mansfield.

The reader's cultural environment is a significant contextual factor in the interpretation of literary texts. A detailed account of culturally influenced reading is given in Ben-Porat (1991), with reference to Israeli readers' interpretations of a 12th-century poem that describes a city of beauty and grandeur,

without naming the city as Jerusalem. Ben-Porat shows how Israeli students given an unseen exercise on the poem easily interpret the reference to Jerusalem, in spite of a rather different experience of the contemporary city. Their readings are attributable to a culturally constructed concept of the city, shaped, in part, by descriptions in other works of literature.

Avant-garde, modernist, and postmodern texts, in which forms and conventions, including linguistic forms, are manipulated to an extent not usually encountered in nonliterary contexts, pose a challenge to the reader of literature. The interpretation of these texts also holds particular interest for the literary pragmaticist. Enkvist (1991), for example, considers more experimental literary texts, such as Dadaist poems, which defy interpretation in the deviation from recognizable linguistic form. He suggests that these genres are simply the endpoint of a literary function which aims to maximize the work entailed in the reading process. For Enkvist, most utterances involve intelligibility (linguistic well-formedness), comprehensibility, and interpretability, but literature, to varying degrees, prioritizes interpretability, sometimes at the expense of the other two factors. The successful reader of literature is able to construct a text world that makes some sense in spite of this difficulty, and the literary text thus gives rise to aesthetic tension.

Conclusion

The examples of pragmatic approaches to literature given here show that the range and purpose of literary pragmatics is wide. Some approaches take the technical apparatus of nonliterary pragmatics as a starting point, arguing that, with some adjustments, a case can be made for considering literary texts in terms of speech act theory, the cooperative principle and the politeness principle. Others abandon the pragmatic models altogether, but still aim to characterize literary effects with reference to literary function and the literary reading process. A central feature in all of the work is its attempt to establish literary works as acts of communication that relate, sometimes obliquely, to acts of communication in nonliterary discourses.

Syntax-Pragmatics Interface: Overview

K Fukushima, Kansai Gaidai University,

Conflicting Priorities

Since the inception of generative grammar, formally oriented researchers have been aware of the significance of pragmatic factors for adequately describing/theorizing about the domain of syntax. Morgan (1975) and Gazdar (1980), for example, pointed to

the inescapable pragmatic influence on sentence structure. This dependency of syntax on pragmatics, however, had largely been ignored by generative syntacticians for quite some time because they had been preoccupied by their quest for universal grammar. In contrast to this, functionally oriented thinkers considered communicative demands to be the primary motivation for grammar. Reflecting this state of affairs, there have been two general, major approaches to the syntax-pragmatics interface. The first is syntactico-centrism, which relegates pragmatics

to the status of a secondary linguistic system, excluded from the self-contained syntactic component (or grammar in general). The second approach is pragmatico-centrism, which relegates syntax to a derivative role and makes pragmatics central. However, a third approach, the syntax-pragmatics alliance, in which different degrees or depths of interaction between syntax and pragmatics are accommodated, has resurfaced recently, in particular from within the generative orientation.

Interface in Retrospect

The Centrality of Syntax

Proponents of syntactico-centrism are Gazdar and Klein (1977), Chomsky (1986), and Carston (1998). These researchers were agnostic about the exact nature of the interaction between syntax and pragmatics (especially the actual mechanisms involved) and treated pragmatics as a postgrammatical filter. Gazdar and Klein allocated a placeholder in the syntactic structure, to be filled with an extragrammatical pragmatic condition to determine the acceptability of the structure. Chomsky (1986) included pragmatics (use of language) as one agendum of linguistic inquiry, but considered the elucidation of language structure (knowledge of language) and its acquisition as having priority status. Carston designated pragmatics as supplying a selection criterion for a particular sentential structure from a set of sentences with equivalent truth conditions (for example, *A dog bit you/You were bitten by a dog/It was a dog that bit you*). The criterion is based on the amount of 'processing effort' in the sense of Relevance Theory (Sperber and Wilson, 1986; see **Relevance Theory**).

The Centrality of Pragmatics

Pragmatico-centrism is represented by Givón (1979) and Hopper (1987). Givón considered that loose, paratactic pragmatic discourse structures (the pragmatic mode) gave rise to tight, grammaticalized syntactic structures (the syntactic mode). The differences between the two are illustrated by the following (nonexhaustive) opposing characteristics: (1) topic-comment versus subject-predicate structure, (2) loose conjunction versus tight subordination, (3) slow versus fast rate of delivery, (4) word-order-based on old/new information versus case functions, and (5) absence versus elaborate use of grammatical morphemes. The opposing pairs are mirrored by the disparities observed between pidgins versus creoles, child versus adult language, and informal versus formal speech. To the extent that the first members

of these pairs are considered to be 'prior,' the primacy of the pragmatic mode is justified. Even more radical is Hopper, who claimed that grammar is 'emergent' in the sense that discourse gives rise to and shapes structure (or regularity) as an ongoing process. An emergent structure is neither determined nor fixed – it is constantly open and in flux. In this view, grammar is simply a name given to certain categories of observed repetitions in discourse.

Classical Attempts at Syntax-Pragmatics Integration

Classical variants of the syntax-pragmatics alliance are the proposals by Ross (1970) and Gordon and Lakoff (1971). Ross suggested that on top of a declarative sentence, there is an extra layer of syntactic projection with a phonetically empty speech act verb taking a null subject (speaker) and object (addressee), as shown in **Figure 1**. His performative hypothesis was an attempt to represent pragmatic aspects as syntactic constituents. However, as is well known, Ross's approach fails to distinguish the following two sentences in terms of truth conditions: *John laughed* (a contingent fact) and *I claim that John laughed* (true when uttered). With the recent development of more elaborate syntactic apparatuses, Ross's idea has been reincarnated, as described in the next section.

Gordon and Lakoff (1971), who employed conversational postulates as a component for a transderivational rule. To derive (1) *why paint your house purple?* from (2) *why do you paint your house purple?*, the conversational postulate 'Unless you have some good reason for doing *x*, you should not do *x*' is supposed to be entailed by the logical structure of (2), a class of contexts, and a set of conversational postulates. Their approach was an attempt to constrain

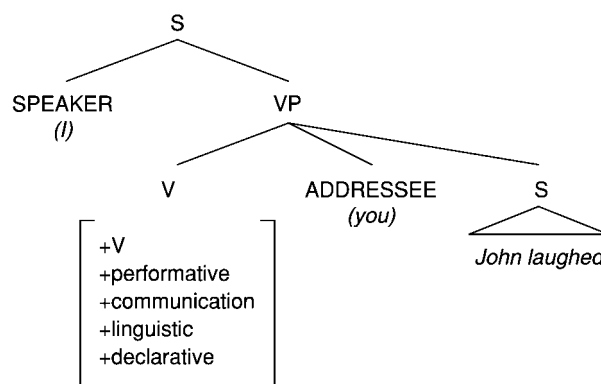

Figure 1 Ross's performative hypothesis: In a declarative sentence, there is an extra layer of syntactic projection with a phonetically empty speech act verb taking a null subject (speaker) and object (addressee).

syntactic derivation pragmatically. According to Green (2004), Gordon and Lakoff confused a speaker's intentions and beliefs with semantic matters of truth. Although it is true that the contextual use-interpretation relation associated with a linguistic form is dependent on the speaker's and addressee's beliefs and intentions about one another's beliefs and intentions, Gordon and Lakoff's approach obscured this aspect.

Pulling All That Together

Syntactico-centrists do not at all deny the relevance of pragmatics for syntax; the interaction between syntax and pragmatics is simply not a central concern for them. But why not? (See Newmeyer, 1998). Also, as suggested by Givón (1995), pragmatic-centrists need to take syntactic structure seriously. After all, some items of the pragmatic mode are made available courtesy of **syntactic** mechanisms assembling constituents in accordance with some ordering or combinatory criteria. Because syntax and pragmatics interact with, influence, and complement one another, it would be desirable if we could devise ways to synthesize the two. Recent attempts at achieving such a goal are illustrated in the next section.

Interface Now: The Syntax-Pragmatics Alliance Revisited

Functional Categories and Pragmatics

With the advent of functional categories in the Chomskyan Principles and Parameters framework (e.g., Agr and D heads projecting AgrP and DP), a path was cleared for the inclusion of abstract syntactic elements in a structural description. Researchers investigating languages with topic-focus structures quickly embraced the creation of pragmatically oriented functional categories (such as Focus Phrase), which opened up possibilities for describing languages, such as Hungarian, that had evaded a rigid English-centered theoretical mold (e.g., Horvath, 1985; Kiss, 1995; see also Szendrői, 2004).

The invention of pragmatically oriented functional heads (as seen, e.g., by Cinque, 1999) soon came to include **syntactic** projections for speech act (*sa*), evaluativity (*eval*), and evidentiality (*evid*) (Speas and Tenny, 2003). As an example embodying such a neoperformative hypothesis, compare Figure 2, which represents a declarative sentence structure projected by the *sa* head. The pragmatic roles, Speaker (the 'agent' of a speech act), Utterance Content (the 'theme'), and Hearer (the 'goal'), are not primitives but defined structurally: Speaker c-commands state of

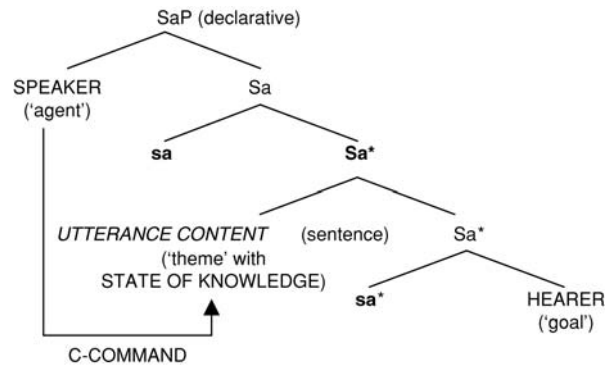

Figure 2 The neoperformative hypothesis: A declarative sentence structure is projected by the speech act head (*sa*, speech act; *sa**, 'lower shell' structure of the SaP. SaP, speech act projection). Adapted from Speas and Tenny (2003).

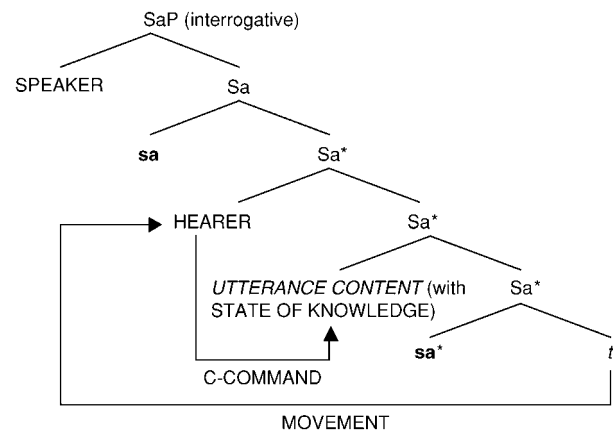

Figure 3 A syntactic transformation deriving an interrogative structure from the declarative structure.

knowledge within utterance content, making Speaker the locus of the point of view. From the declarative structure, a syntactic transformation derives an interrogative structure, as shown in Figure 3. Hearer is now the closest c-commander for state of knowledge and the point of view is attributed to Hearer. Imperative and subjunctive *sa* structures are shown in Figures 4 and 5 respectively.

The motivation for such speech act projections (SaPs) is the fact that languages, out of many possible illocutionary acts, grammaticalize only up to five or six distinct types. More significantly, there appear to be agreement-like phenomena involving Speaker and Hearer, for example, the Arabic complementizer *inna* and the morpheme *nuwa* in Mupun (Mwaghavul), respectively.

What is peculiar about SaPs is the lack of correspondence between actual speech acts and the particular, syntactically defined speech act structures. Thus, the Utterance Content of any syntactic type (*modulo*

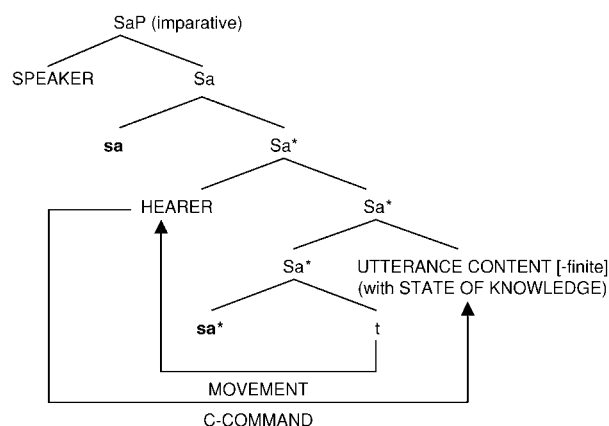

Figure 4 A syntactic structure for an imperative sentence.

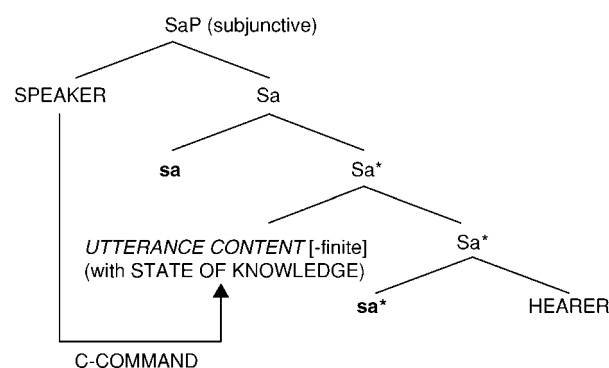

Figure 5 A syntactic structure for a subjunctive sentence.

the choice of tense) can, in principle, be embedded under a given SaP, and its speech act property is determined by the SaP's configurational characteristics. Because, for example, Speas and Tenny recognized the multifunctionality (claim, promise, request, etc.) of the declarative SaP, they needed but lacked an additional interpretive mechanism to determine the **actual** speech act type of the SaP.

Let us consider the following direct/rhetorical question: *Who can defeat Godzilla?* Embedding this within either the interrogative or declarative SaP structure seems to superficially guarantee the desired interpretations. Why, then, can the imperative sentence, *(you) beware of Godzilla!*, not be subjunctive (since both are [-finite])? The difference between the two seems to hinge on their pragmatically determined conventional use. This means that, to obtain proper embedding of Utterance Content within an SaP structure, the speech act type of Utterance Content needs to be determined **prior to** such embedding. That seems to render the pragmatic relevance of SaP structures questionable. Speas and Tenny appeared to be

preoccupied with a narrow range of pragmatico-syntactic phenomena (e.g., agreement, point of view, etc.); also, they seemed to be hampered by their **exclusive** reliance on syntactic concepts, from which pragmatic notions are **unidirectionally** obtained as derivatives.

An Inclusive Theory of Grammar and Pragmatics

Another way to implement the syntax-pragmatics alliance is by employing what Fukushima (2002) called an “inclusive theory of grammar,” such as a framework like Head-Driven Phrase Structure Grammar (HPSG) (see Pollard and Sag, 1994; Sag *et al.*, 2003). Here, grammar is a collection of linguistic constraints on lexical and nonlexical linguistic signs (words and phrases), expressed via feature structures (with FEATURE-value pairs). The linguistic constraints are **both** grammatical (phonology, category, and content) **and** pragmatic (context). An example of such a set of constraints or properties is the lexical sign *John* in Figure 6. The sign *John* satisfies the following constraints: It is a noun (syntax), used to refer to a third-person singular referent (semantics), who bears the name *John* (pragmatics). (The shared structures are indicated in Figure 6 by [1], showing the identity of feature values.) In such a feature structure, linguistic constraints are imposed on linguistic signs **simultaneously and nondirectionally**. No privilege, for example, is given to syntactic over pragmatic information.

Let us see how such a framework can be called on to handle speech acts. The illocutionary force of warning, for example, is rendered as in Figure 7. It says that a linguistic sign with the phonological shape [1] can be uttered by a speaker [2] to an addressee [3]. This is done in order to bring about a state of affairs in which the speaker's uttering [1] to the addressee results in the addressee's becoming aware of a danger, originating from some unspecified element [4]. Thus, the same technical apparatus both is used as a grammatical description and serves to elucidate illocutionary conditions.

Based on this, we can account for the behavior of lexical items with restricted syntactic distribution, such as the verb *beware*: *Beware of Godzilla!* and *I want you to beware of Godzilla* but not **I'm confident I'll beware of Godzilla*. As part of its lexical definition, *beware* makes reference to the pragmatic condition on warning in Figure 7, as indicated in Figure 8. The lexical definition tells us that *beware* is a verb that is used uninflected and takes two arguments, NP_[3] and PP_[5]. The subject [3] watches out for the object [5], and the speaker [2] believes that the object endangers the subject.

An extended version of HPSG simultaneously accommodates constructional (syntactic), clausality (semantic), and illocutionary (pragmatic) aspects of sentences (Ginzburg and Sag, 2000; Ginzburg *et al.*, 2003, the latter another instance of the neo-performative hypothesis) and allows us to solve our previous question-imperative dilemma. First, the *illocutionary-relation* type *ask-relation* is normally associated with a *clausality* type *question*. Given that there is no contextual infelicity, the direct question is simply a question. Second, the *illocutionary-relation* type *assert-relation* is normally associated with the *clausality* type *proposition*. One illocutionary condition (similar to Figure 7) that is associated with the direct question construction allows it to

be a rhetorical question. With that, a conversational implicature (in *BACKGROUND*) – arising from the fact that uttering the direct question (*ask-relation*) in a given context is insincere – helps establish a new connection between the *illocutionary-relation* type *assert-relation* and the clausality type *question*, overriding the default association between *ask-relation* and *question* (see **Implicature**). In contrast, no illocutionary condition would allow the imperative construction (of the *clausality* type *outcome*) to be compatible with subjunctive use. This type of account is available due to the inclusiveness of the HPSG architecture, in which grammatical information and pragmatic information can be brought together and synthesized under a single structural representation.

Figure 6 An inclusive theory of grammar: The lexical sign *John* as a set of constraints.

Summary

A syntactic theory that claims to be a viable basis for explaining language use in real time cannot avoid the issue of the syntax-pragmatics interface. After some 30 years of neglect, attempts have now resumed to identify the proper ways of approaching the problems existing in this domain (although so far, no definitive conclusions have been reached). Such attempts need to consider (nonexhaustively) questions regarding

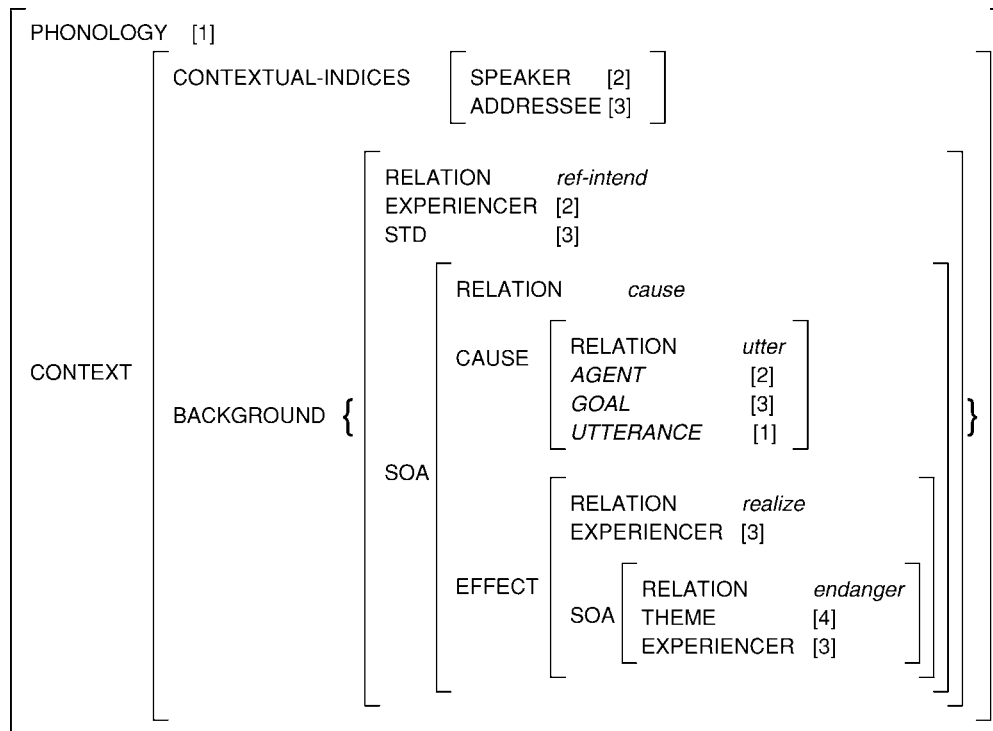

Figure 7 The illocutionary force of warning; SOA (state of affairs) is roughly equivalent to a proposition, and ref-intend is shorthand for the sequence of predicates *intend-recognize-intend-believe*. Adapted from Green (2000).

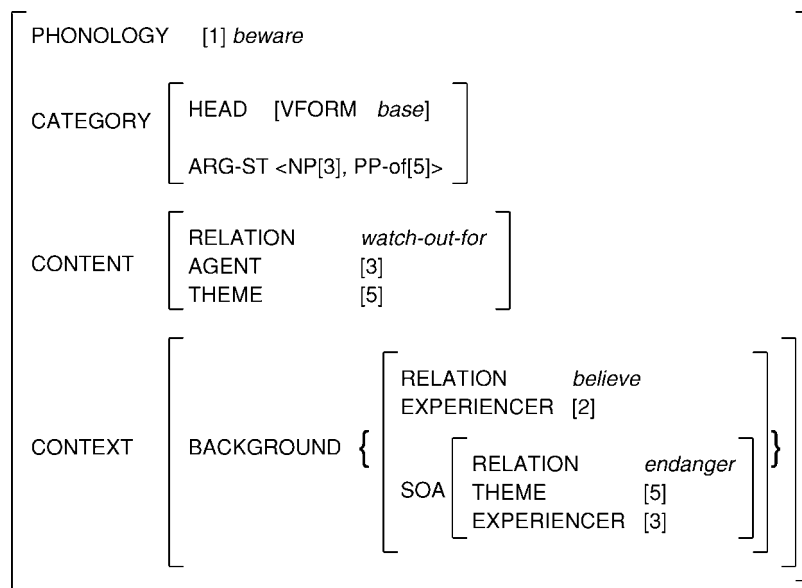

Figure 8 The lexical definition of *beware*. Adapted from Green (2000).

(1) ways of representing pragmatic information in conjunction with a structural description; (2) ways of accommodating the psycholinguistic properties of language processing, in particular incrementalness and speed; and (3) the adequacy of the performative hypothesis (see Kühnlein *et al.*, 2003b).

Systemic Theory

Origins of Systemic Theory

Systemic, or systemic–functional, theory has its origin in the main intellectual tradition of European linguistics that developed following the work of Saussure. Like other such theories, both those from the mid-twentieth century (e.g., Prague school; French functionalism) and more recent work in the same tradition (e.g., that of Hagège), it is functional and semantic rather than formal and syntactic in orientation, takes the text rather than the sentence as its object, and defines its scope by reference to usage rather than grammaticality. Its primary source was the work of J. R. Firth and his colleagues in London. As well as on other schools of thought in Europe such as glossematics, it also draws on American anthropological linguistics, and on traditional and modern linguistics, and on traditional and modern linguistics as developed in China.

Its immediate source is as a development of scale and category grammar. The name 'systemic' derives from the term 'system,' in its technical sense as defined by Firth (1957); system is the theoretical representation of paradigmatic relations, contrasted with 'structure' for syntagmatic relations. In Firth's system–structure theory, neither of these is given priority; and in scale and category grammar this perspective was maintained. In systemic theory the system takes priority; the most abstract representation at any level is in paradigmatic terms. Syntagmatic organization is interpreted as the 'realization' of paradigmatic features.

This step was taken by Halliday in the early 1960s so that grammatical and phonological

representations could be freed from constraints of structure. Once such representations were no longer localized, they could function prosodically wherever appropriate. The shift to a paradigmatic orientation added a dimension of depth in time, so making it easier to relate language 'in use' to language being learnt; and it enabled the theory to develop both in reflection and in action – as a resource both for understanding and for intervening in linguistic processes. This potential was exploited in the work done during the 1960s on children's language development from birth through their various stages of schooling.

Systems and Their Realization

The organizing concept of a systemic grammar is that of choice (that is, options in 'meaning potential'; it does not imply intention). A system is a set of options together with a condition of entry, such that if the entry condition is satisfied one option, and one only, must be chosen; for example, in English grammar, [system] 'mood,' [entry condition] finite clause, [options] indicative/imperative. The option selected in one system then serves as the entry condition to another; e.g., [entry condition] indicative, [options] declarative/interrogative; hence all systems deriving from a common point of origin (e.g., [clause]) are agnate and together form a 'system network.' At the present stage of development, system networks for English grammar in computational form contain about 800 systems. An entry condition may involve the conjunction of different options; hence a system network is not a taxonomic structure but has the form of a lattice.

The system has one further component, namely the 'realization statement' that accompanies each option. This specifies the contribution made by that option to the structural configuration; it may be read as a proposition about the structural constraints associated

with the option in question. Realization statements are of seven types:

1. 'Insert' an element (e.g., insert subject);
2. 'Conflate' one element with another (e.g., conflate subject with theme);
3. 'Order' an element with respect to another, or to some defined location (e.g., order finite auxiliary before subject);
4. 'Classify' an element (e.g., classify process as mental: cognition);
5. 'Split' an element into a further configuration (e.g., split mood into subject + finite);
6. 'Preselect' some feature at a lower rank (e.g., preselect nominal group: human collective); and
7. 'Lexify' an element (e.g., lexify subject: *it*).

When paths are traced through a system network, a 'selection expression' is formed consisting of all the options taken up in the various functional components. As the network is traversed, options are inherited, together with their realizations; at the same time, new realization statements continue to figure throughout. The selection expression constitutes the grammar's description of the item (e.g., the particular clause so specified); it is also, by reference to the network, the representation of its systemic relationship to other items in the language – since the grammar is paradigmatic, describing something 'consists in' locating it with respect to the rest (showing its total lineage of agnate forms).

Other Basic Concepts

Systemic theory retains the concepts of 'rank,' 'realization,' and 'delicacy' from scale and category grammar. 'Rank' is constituency based on function, and hence 'flat,' with minimal layering; 'delicacy' is variable paradigmatic focus, with ordering from more general to more delicate; 'realization' (formerly 'exponence') is the relation between the 'strata,' or levels, of a multistratal semiotic system – and, by analogy, between the paradigmatic and syntagmatic phases of representation within one stratum. But in systemic theory, realization is held distinct from 'instantiation,' which is the relation between the semiotic system (the 'meaning potential') and the observable events, or 'acts of meaning,' by which the system is constituted.

The shift to a paradigmatic orientation led to the finding that the content plane of a language is organized in a small number of functionally defined components which Halliday labeled 'metafunctions.' According to this theory the grammar of natural languages evolved in simultaneously (a) 'construing' human experience (the 'experiential' metafunction)

and (b) 'enacting' interpersonal relationships (the 'interpersonal' metafunction), both these being underpinned by (c) the resources of (commonsense) logic (the 'logical' metafunction; (a) and (c) are grouped together as 'ideational'). The stratal role of the lexicogrammar lies in mapping these semantic components into a unitary construct, one that is capable of being linearized; in doing this, the grammar (d) 'creates' its own parallel universe in the form of discourse (the 'textual' metafunction). These metafunctions define the dimensions of semantic space; and since they tend to be realized by different structural resources – experiential meanings segmentally, interpersonal meanings prosodically, logical meanings in iterative structures, and textual meanings in wave-like patterns – they also determine the topological formations that are characteristic of human speech.

A systemic grammar is therefore 'functional' in three distinct though related senses:

1. Its 'explanations' are functional: both the existence of grammar (why grammar evolved as a distinct stratum), and the particular forms that grammars take, are explained in terms of the functions that language evolved to serve.
2. Its 'representations' are functional: a structure is an organic configuration of functions, rather than a tree with nodes labeled as classes.
3. Its 'applications' are functional: it developed as an adjunct to practices associated with language use, requiring sensitivity to functional variation in language ('register' variation). These considerations both relate it to, and at the same time distinguish it from other functional theories.

Other Features of the Theory

Like the Firthian linguistics from which it evolved, systemic theory is oriented towards language as social process; the individual is construed intersubjectively, through engagement in social acts of meaning. This is not incompatible with a cognitive perspective, which has been adopted in some systemic work (notably Fawcett 1980); but it does rule out any claim for 'psychological reality.' Halliday formulated this general stance as 'language as social semiotic,' thereby also locating systemic theory in the thematic context of semiotics, defined as the study of systems and processes of meaning. The relation between language and other sociocultural phenomena is then modeled on that of realization (the perspective here is Firthian rather than Hjelmslevian): language 'realizes' culture in the way that, within language, sound realizes wording, and the realization of wording in sound, in its turn, realizes meaning.

It follows from this that systemic theory gives prominence to discourse, or 'text'; not – or not only – as evidence for the system, but valued, rather, as constitutive of the culture. The mechanism proposed for this constitutive power of discourse has been referred to as the 'metafunctional hookup': the hypothesis that (a) social contexts are organic–dynamic configurations of three components, called 'field,' 'tenor,' and 'mode': respectively, the nature of the social activity, the relations among the interactants, and the status accorded to the language (what is going on, who are taking part, and what they are doing with their discourse); and (b) there is a relationship between these and the metafunctions such that these components are construed, respectively, as experiential, as interpersonal, and as textual meanings. Register, or functional variation in language, is then interpreted as systemic variation in the relative prominence (the probability of being taken up) of different options within these semantic components.

In fact such register variation (spoken/written, commonsense/technical, transactional/expository, ... and so on) lies on the continuum between system and text; the characteristic of systemic work is that it brings all parts of this continuum under focus of attention. Analogously, it encompasses both speaker and listener perspectives (in computational terms, text generation, and parsing – there are, for example, no nonrecoverable operations such as deletion), and both synoptic and dynamic orientations; and uniquely among current theories, it assigns as much value to interpersonal and textual meaning as to ideational. On the other hand, in other respects systemic work is notably ill-balanced; there has been little study of morphology and phonology, and a disproportionate amount of research relates to English. These reflect on the one hand the contexts of its own development, especially the kinds of application for which it has been sought out; and on the other hand its requirement of comprehensiveness, demanding a coverage which is at once both broad and deep.

Development of Systemic Theory

The outlines of systemic theory were formulated in London in the 1960s by Halliday together with Huddleston, Hudson, and others, and others, and in application to Bernstein's work by Hasan, Mohan, and Turner; other significant input came from the application of systemic concepts in curriculum development work, in the analysis of scientific writings and of natural conversation, and in descriptions of a number of Asian and African languages. The theory was further developed in the 1970s: by Fawcett,

Berry, and Butler in the UK; by Halliday and Hasan in Australia; and by Gregory and his colleagues in Toronto. Since 1980 systemic work has expanded considerably in various directions (artificial intelligence, child language development, discourse analysis and stylistics, and language education). It is typical of systemic practice that major extensions both to description and to theory have taken place in these 'applied' contexts; for example, the very large systemic grammars of English that now exist in computational form (PENMAN 'Nigel'; COMMUNAL), and the extensive studies of children's writing and of the language of educational texts in science, history, and other subjects that have been carried out by Martin and his colleagues in contexts such as the New South Wales Disadvantaged Schools Program.

Since 1980, further studies have been devoted to languages other than English, notably Chinese (Fang; Hu; Long; McDonald; Ouyang; Zhang; Zhao; Zhu), French (Caffarel), Indonesian (Sutjaja; Wirnani), and Tagalog (Martin); and work in text generation has begun to take in Chinese and Japanese (Matthiessen *et al.*) and German, French, and Dutch (Bateman; Steiner). In English, Halliday's *Introduction to Functional Grammar* brought together some of his studies begun in the late 1960s (1967/68); and advances were made in all areas of the grammar: experiential (Davidse; Martin), interpersonal (Butler; Thibault), and textual (Fries; Hasan; Matthiessen). Matthiessen (1992a) presented a system-based account of English grammar, deriving from materials he had written to accompany the 'exporting' of Nigel.

Many general theoretical discussions have appeared (Fawcett; Halliday; Lemke, etc.), as well as new theoretical underpinning of key areas, especially lexicogrammar, discourse semantics, and text structure (Matthiessen; Martin; Berry; Hasan, etc.). Matthiessen's (1992b) account of register theory emphasizes the integrative character of systemic work: while there are often alternative interpretations, especially where new problems are being addressed, these are not detached from their overall context in language and in linguistics. Thus there is no disjunction between grammar and discourse, or between the system and the text.

With the strengthening of what Halliday calls the 'grammatics' (that is, theory of grammar as metatheoretic resource), systemic writings have increasingly foregrounded the constructive power of grammar; this is reflected in numerous studies which began with the 'critical linguistics' of the late 1970s (Fowler *et al.*; Kress and Hodge; subsequently Butt; Hasan; Kress; Lemke; Martin; McGregor; O'Toole; Thibault; Threadgold; cf. Threadgold *et al.*, 1986, and the journal *Social Semiotics*). In a large-scale investigation of natural conversation between

mothers and their preschool children, Hasan and Cloran (1990) have developed semantic networks to explore the effects of social factors on children's learning styles, and their consequences for education. Martin's work on register and genre (1992) extends the constructivist model of language to include strata of genre and ideology. It is in this overall perspective that language becomes central to the educational initiatives of Martin, Rothery, Christie, and others in Australia; compare also the work of Carter *et al.* in the LINC ('Language in the National Curriculum') program in the UK.

In 1974 Fawcett organized the first systemic workshop, at the West Midlands College of Education, with 16 participants from four centers in the UK. Since then the workshop has been an annual event; the first international workshop was the ninth, held in Toronto (York University) in 1982. In the 1990s, now as 'International Systemic (or Systemic-Functional) Congress,' meetings have been held at the University of Stirling (1990) and at the International Christian University in Tokyo (1991); in addition, regular national systemics seminars are held in Australia, in the UK, and in China. The newsletter *Network* provides information on these activities, along with short articles, reviews, bibliographies, and conference reports. The regularly updated *Select Bibliography of Systemic Linguistics* now lists about 800 books and articles. Selected conference papers from 1983, 1985, 1986, 1988, 1989, and 1990 have appeared in published form (see Bibliography).

Influences and Trends

In the period from its inception in the early 1960s the main influences on systemic theory (other than those coming in via specific applications such as computational linguistics) have come from Lamb's work in stratificational grammar and from Sinclair's in discourse and in lexical studies. Lamb and Halliday collaborated regularly over a number of years. Sinclair had been an originator of scale and category grammar and his subsequent work exploited this, though in a complementary direction to Halliday's: Sinclair builds the grammar out of the lexis, whereas Halliday builds the lexis out of the grammar. Other input has come from Labov's quantitative methodology (though not his general perspective on language and society); from the theory and practice of corpus linguistics (Quirk; Svartvik *et al.*; more recently Sinclair); from other work in functional linguistics (especially Thompson); and from poststructuralist semiotics in general.

A feature of systemic work is that it has tended to expand by moving into new spheres of activity, rather

than by reworking earlier positions. This reflects an ideological perspective in which language is seen not as unique or *suigeneris* but as one aspect of the evolution of humans as sociocultural beings. Thus input often comes from outside the discipline of linguistics: from current theories in fields such as anthropology, literature, and neurology, and from developments in more distant sciences. Much systemic linguistics reflects transdisciplinary rather than disciplinary thinking in its approach to problems of language.

This orientation appears in some present trends and likely future directions.

For example:

- Systemic grammatics as model for other semiotic systems, especially forms of art: not only literature (Butt; O'Toole; Thibault; Threadgold) but also music (van Leeuwen; Steiner), visual imagery (Kress and van Leeuwen), and painting, architecture, and sculpture (O'Toole).
- Further developments of register theory to investigate the linguistic construction of knowledge and structures of power.
- Using available corpus data and programs to test hypotheses about the probabilistic properties of systems (Nesbitt and Plum; Halliday and James).
- Further development of language-based educational programs, in initial literacy, secondary 'subjects,' teacher education, language in the workplace, etc.
- Natural language processing, modeling systems of meaning (knowledge systems), and developing integrated generation and parsing programs, including multilingual ones.
- Further work in deaf sign (Johnston) and development of systemic research in neurolinguistics and the discourse of aphasia, dementia, etc.
- Greater emphasis on studies of the expression plane in a general systemic context.

Just as systemic theory is itself a variant of a broader class of theories (functional theories, perhaps with 'system-structure theories' as an intermediate term), so it itself accommodates considerable variation. Gregory's 'communication linguistics' foregrounds structures of knowledge and presents a dynamic 'phase and transition' model of discourse; Fawcett's computational modeling contrasts in various ways with that of Matthiessen and Bateman; Martin's register theory, with genre as a distinct stratum, contrasts with Hasan's view of register as functional variation realizing different values of contextual variables. This kind of variation in 'metaregister' is one of many ways in which systemic theory appears as a metaphor for language itself.

The standard introduction to systemic linguistics has been Berry (1976/77). Other introductory or

summary works are Monaghan (1979), Halliday and Martin (1981), Butler (1985), Morley (1985), and, an original work in Chinese, Hu *et al.* (1989). The work now appearing with the New South Wales Disadvantaged Schools Program is an excellent source for the systemic grammar of English, as also is Butt *et al.* (1990–); other workbooks are in the course of preparation. Three further introductory studies that are largely completed are Halliday and Matthiessen, on the history of systemic linguistics; Matthiessen and Halliday, a general account; and Thibault, on grammar and discourse. These will give an overview of theory and practice as current in the mid-1990s.

Tacit Knowledge

G S Rattan, University of Toronto, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

As Louise Antony and Norbert Hornstein (2003: 6) suggest, two of Chomsky's most significant philosophical contributions lie in his revival of mentalism in the philosophy of mind and rationalism in epistemology. Linguistics is the study of the system of knowledge possessed by speakers both innately and in the relatively steady state condition of linguistic maturity. This knowledge is a kind of tacit knowledge. The aim of this article is to clarify some of the psychological and epistemic aspects of tacit knowledge, primarily as it is relevant to Chomskyan linguistics. As a psychological attitude, tacit knowing is distinguishable both from garden-variety kinds of propositional attitudes like believing and desiring (what I call full propositional attitudes) and from nonpropositional states or skills typically classified as instances of knowing how. The epistemic role of tacit knowledge in the broader issue of knowledge of meaning is discussed, and a more positive understanding of tacit knowing, with its distinctively epistemic gloss, is tentatively offered.

The Early Debate

It was clear to both Chomsky and his early critics that the kind of knowledge of language that speakers possess, if any, is not explicitly held. Speakers do not know explicitly the general principles to which human languages conform, or the grammars of the specific languages of which they are speakers. Chomsky and his early critics differed, however, on what they took to be the implications of that straightforward idea.

Critics argued that the invocation of psychological attitudes, especially knowing, was at best misleading and at worst wrong. The general objection is that the cognitive relation involved in the explanation of linguistic capacity, if indeed there is such a cognitive relation, cannot be that of knowing, because that

cognitive relation does not sustain the connections constitutive of knowledge (see, e.g., Stich, 1971: §4; Quine, 1972: 442; Devitt and Sterelny, 1999: 139; Dummett, 1991: 95–97). More specifically, early critics held that the states that underlie our ability to use language are, for most competent speakers, wholly unconscious, and when known, say by linguists, are known only indirectly through scientific theorizing. But, they contend, if one is to be ascribed a certain piece of knowledge, that knowledge should be recognizable 'from the inside' and not merely ascribable as a result of scientific theorizing. Let us say that having a full propositional attitude is constrained by a 'self-knowledge constraint,' according to which self-knowing is a distinctive, nontheoretical way of coming to know of one's attitudes and their contents.

Chomsky considers such objections (Chomsky, 1980, 1986) and replies as follows:

I have been speaking of "knowing English" as a mental state ... [But] to avoid terminological confusion, let me introduce a technical term devised for the purpose, namely "cognize," ... In fact I don't think that "cognize" is very far from "know" ... [Cognizing] is tacit or implicit knowledge, a concept that seems to me unobjectionable ... Cognizing has the structure and character of knowledge, but may be and in the interesting cases is inaccessible to consciousness. (Chomsky, 1980: 70–71)

The thrust of Chomsky's answer, then, is that if 'knowledge' offends, a technical term can be employed whose sense lacks precisely the offending features; but, continuing the response, the theoretical concept thereby introduced ought not to be thought of as fundamentally different from knowledge: it is knowledge, but it is unconscious, or not self-known.

Tacit Knowing vs. the Full Propositional Attitudes

We can see here an oversimplification of what might be involved in an account of the nature of propositional attitudes. There seems to be room

to acknowledge both that speakers' knowledge of language does not sustain the connections constitutive of knowledge and the full propositional attitudes and that, nevertheless, tacit knowledge is unobjectionable. The debate is oversimplified in turning only on a single, blunt constraint of self-knowledge. In what follows, I will try to enrich the debate by indicating considerations for thinking of tacit knowing as a propositional attitude without construing it as a full propositional attitude.

What more might be added to the understanding of the fully propositionally attitudinal to bring out its deep constitutive differences with tacit knowing? To begin with, we may take note of a pervasive feature of cognitive psychological theorizing, namely, that it construes the mind as modular: as segmented into mental components that use systems of encapsulated information that are inaccessible to conscious thinking, that are dedicated to representing highly structured or eccentric domains, and whose deployment is fast and mandatory (cf. Fodor, 1983). For the proponent of the idea that knowledge of language is a kind of tacit knowledge, the language faculty is itself, to a first approximation, such a modular system (Chomsky, 1986: chapter 1 [especially note 10]; Higginbotham, 1987).

The general properties of modular systems stand in sharp contrast with basic properties of the full propositional attitudes. The full propositional attitudes are inferentially integrated (Stich, 1978; Evans, 1981) and so can draw upon, and can be drawn upon, by a range of other full propositional attitudes (so they are neither encapsulated nor inaccessible) without regard to subject matter (so they are not dedicated). Although belief fixation may not be voluntary, it seems not to be mandatory in the sense in which the operation of modular systems is. The latter is a compulsion by psychological law; the former is something like a compulsion by reason (more on this below). Finally, the operation of the full propositional attitudes can be painfully slow. Reasoning can take a long time. These differences show that, on its own, the self-knowledge constraint is quite incomplete as to what is distinctive about the way that the information contained in the language faculty is held.

The point about modularity concerns primarily the nature of the attitude of tacitly knowing. But consider as well what Gareth Evans (1982) has called the 'generality constraint,' which pertains to the objects of the full propositional attitudes, thoughts or propositions, and their constituents, concepts. According to the generality constraint, concepts possess an inherent generality that mandates their recombining with appropriate concepts of other logical categories;

slightly more formally, thoughts are closed under logico-syntactic formation rules, up to conceptual incoherence or anomaly (cf. Peacocke, 1992: 42).

Now, no explanatory point seems to be served by imposing such a constraint on the representation of the information deployed in the language faculty. Speakers tacitly know the grammar that they do; knowledge of that grammar is deployed in some way or other, through the actions of mechanisms implementing algorithms that deploy the grammatical information tacitly known, so as to allow the acquisition, production, and perception of linguistic forms. Insisting that the constituents of the representation of linguistic information be subject to the generality constraint in no way illuminates the explanatory role of tacit knowing.

The reason can be clarified by thinking about the basic theoretical aims and motivations for both the full propositional attitudes and their contents. The full propositional attitudes and their contents are the fundamental theoretical entities in the conceptualization and explanation of the epistemic and practical successes and failures of agents. The explanations trace and assess the complexes of reasons for which agents believe and act, and implicitly evaluate those complexes, and agents, against an ideal of rational epistemic and practical functioning. The notions of epistemic and practical responsibility get their grip here, in the gap between actual and ideal. Since rational inference requires the interactions of attitudes and the recombination of concepts in a variety of ways, attitudes and contents must be such as to sustain the actual evaluations of epistemic status of agents in their inferential practices (Rattan, 2002: §4). The requirements that the full propositional attitudes be inferentially integrated and that concepts obey the generality constraint reflect these normative dimensions of the roles of attitudes and contents.

These ideas suggest, then, a deep point of contact with the self-knowledge constraint: that constraint will be relevant, like inferential integration and generality, insofar as it reflects fundamental features of rational practice. And surely it does. Reflecting on one's attitudes is a way of increasing the rational status of those attitudes. But if reflection plays that rational role, then it must be that our access to our attitudes is reliable and possessed of entitlement (cf. Burge, 1996); our access to our own minds must in the most basic cases be knowledge. Demanding that the attitudes and their contents be self-known, then, is part of a general account of the full propositional attitudes and their contents that construes them so that they may play their role in conceptualizing and explaining the normative statuses of agents.

Tacit Knowing vs. Knowing How

But it may be objected that for all that has been said so far, tacit knowing may not be a kind of content-bearing state at all; given the deep differences between tacit knowing and the full propositional attitudes, tacit knowing simply seems not to be a genuine mental attitude toward contents.

The objection can be elaborated by insisting that speaking a language is not a matter of knowing propositions at all. As Michael Devitt and Kim Sterelny put it:

[C]ompetence in a language does not consist in the speaker's semantic propositional knowledge of or representation of rules. It is a set of skills or abilities ... It consists in the speaker being able to do things with a language, not in his having thoughts about it. (Devitt and Sterelny, 1999: 187)

Perhaps there are no states of knowing the facts about the language – no knowing the rules or grammar of the language. A speaker no more knows the rules of the grammar than one who can ride a bike knows the laws of mechanics governing balance and maneuver. The language faculty is a faculty of knowing how to speak a language. Call the proponent of such a view the 'knowing-how theorist.'

Of course it cannot be denied that speakers do know how to speak the language; but the knowing-how theorist must justify the idea that attributions of knowing **how** are not just species of attributions of knowing **that**, as certain syntactic and semantic evidence suggests (Stanley and Williamson, 2001). Again, it looks as though the knowing-how theorist simply misses the point: although speakers know how to speak the language, that is not an explanation, but a description of what needs to be explained (cf. Higginbotham, 1994). But let us suppose that the knowing-how theorist is proposing an alternative explanation, one that does not appeal to tacit knowing. The knowing-how theorist has at least two significant hurdles to overcome.

First, suppose it is granted that tacit knowing does not have the direct role in rationalizing conceptualizations and explanations that the full propositional attitudes do. There still seems to be nothing to prevent thinking of tacit knowings as having the same attitude-content structure that the full propositional attitudes do. The attitude is not, admittedly, understood as playing a certain rational role, but it still may have a regular and lawlike causal role, and that would seem to be enough to think of there being something attitude-like – a distinctive way in which the information is held – in the picture. (Indeed this is the usual understanding of the attitudes in causal functionalism;

see, for example, Lewis, 1972.) This, for example, is what we might like to say about animals and their attitudes. They fail to have states that satisfy the normative constraints that the full propositional attitudes do, but it would be theoretically heavy handed to say that they do not have states that are very much belief- and desire-like.

Again, serving the aims of rationalizing explanations may require that contents be individuated at the level of Fregean sense rather than reference; this is the point of 'Frege's Puzzle' (Frege, 1892). But if tacit knowings fail to figure directly in these kinds of rational phenomena, then their contents may legitimately be exempted from having the general properties that the contents of attitudes that do so figure must have. The contents of tacit knowings may be Russellian, or have a limited need for cognitive difference without difference in reference. These constituents of contents, objects and properties, presumably do not obey the generality constraint, so there are ways in which contents may be involved yet fail to be like the contents of the full propositional attitudes. The issues here are complex, and I mean only to flag the general issue about the individuation of the contents of tacit knowings and how that may serve to distinguish them from the contents of the full propositional attitudes.

Second, perhaps the proponent of knowing how thinks that the explanation of linguistic ability is merely dispositional, like the explanation of the shattering of a glass by appeal to its fragility. Here, there is some categorical, microstructural, property of the glass that, simplifying tremendously, explains why in conditions of the appropriate sort, the glass shatters. In a like manner the knowing-how theorist may appeal to the categorical neurophysiological ground of linguistic dispositions as comprising a nonintentional explanatory level. This idea, however, is subject to all the general objections that favor functional explanations over neurophysiological ones. It neglects a tradition of thinking about psychological explanations as involving multiple – computational, informational, algorithmic, and implementational – levels (see Marr, 1982; Peacocke, 1986). Indeed the functional states will be realized by neurophysiological states, but the explanation will be cashed out at some level that abstracts from neurophysiological description.

What Is Tacit Knowledge?

So far tacit knowing has been negatively characterized, by being distinguished from both the full propositional attitudes and knowing how. But how are we to understand the nature of tacit knowledge in more

positive terms? Tacit knowing plays a role in the explanations of linguistic acquisition, perception, and production. The described capacities are epistemic in character. Their explanations are part of more elaborate explanations that seek to understand the general phenomenon of communication, including its substantial pragmatic elements. To keep the discussion manageable, I will ignore the more elaborate problems. As well, I will focus only on the problems of linguistic perception and linguistic production. I mean only to gesture roughly at the kinds of considerations that are involved.

According to these explanations, speakers are able to make knowledgeable sound-meaning pairings for sentences because they have information about the phonological, syntactic, and semantic – grammatical – properties of the expression-types that make up those sentences. This information is drawn on by perceptual and production mechanisms. Simplifying immensely, production mechanisms take inputs from intentions to say that *p*, and make available to a speaker, through the use of the grammatical information, expression types that mean that *p*. Perceptual mechanisms take acoustic inputs and, through the use of grammatical information, impose grammatical properties on them, eventuating in an experience of meaning, on the basis of which meaning judgments are made (cf. Fricker, 2003). A fully fleshed out epistemology of meaning would explain the epistemic differences between knowing one's own meaning in production and knowing others' meanings in perception by, for example, considering how the inputs to production and perception, respectively, allow for different kinds of mistakes in the eventuating judgments about meaning.

Let us assume that information is deployed in speakers' linguistic epistemic achievements (so these achievements are not examples of knowing how), and that this information is tacitly rather than explicitly held (so it is not an example of a full propositional attitude). Still, why must we accept that this information is known rather than just truly believed? The question is difficult and fundamental. I offer here some potential lines for understanding.

Suppose, as I have been suggesting, that tacitly held information or content is involved in the explanation of linguistic capacities. Two things are of note here about this information. First, these representations have been formed by a reliable mechanism – one that uses speakers' innate representations of Universal Grammar – that reproduces the grammatical information represented in the minds of speakers in one's community. In normal environments, acquiring these representations will equip one to come to judge knowledgeably the meanings of other speakers.

Second, once one moves away from folk conceptions of public language, it is plausible to think of the facts about which language one speaks as settled by one's grammatical representations or I-language (Chomsky, 1986: Chapter 2; Higginbotham, 1991; Barber, 2001). Judgments about what one means oneself will then be reliably produced, again as outlined above; and since the facts about one's language are determined by one's grammatical representations, they will be reliably produced by the facts that determine the language one speaks. It seems that as a phenomenon at the level of the full propositional attitudes, knowing our own meanings and knowing the meanings of others, when we do, is not an accident.

We can think of the foregoing as giving the outlines of a philosophical explanation of what might be called the success-presupposing features of the explanation of our linguistic capacities. The explanations are not success neutral (see Burge, 1986, who attributes the phrase to Bernard Kobes), in that the explanations are explanations of epistemic capacities that are generally presumed to be successful. But if that is right, we are in a position to say something about why the information tacitly held is knowledge. Unless that information were known, rather than just truly believed, it would seem to be a mystery why drawing on that information in perception and production leads in general to knowledge. So one suggestion is that the status of the information as knowledge comes from the distinctive explanatory role of the tacitly held information in explanations of our generally epistemically successful linguistic capacity.

That's one pass at vindicating the attribution of knowledge. But perhaps something deeper can be said. Here we can return to Chomsky's rationalism. Sometimes Chomsky's rationalism seems to be a genetic rationalism that emphasizes the innate character of Universal Grammar, vindicating an early modern doctrine of innate ideas. But there is another way to think of this rationalism, in which it emerges as a more full-blooded epistemic doctrine. In this way of thinking, at some point in the evolution of humankind, minds came into a cognitive relation with certain abstract structures, with very valuable combinatorial properties. These abstract structures are languages. We have already seen that the tacit is not the realm of epistemic and practical responsibility. So the status of knowledge for tacit representations will not accrue as a result of some personal-level achievement. The status of knowledge for the representations that underlie our linguistic capacity derives instead from a natural attunement of the modular structures of the human mind to the abstract combinatorial structures of language.

Tannen, Deborah

C Kakava, University of Mary Washington,
Fredericksburg, VA, USA

© 2006 Elsevier Ltd. All rights reserved.

One of the most prominent sociolinguists and discourse analysts, Deborah Tannen has contributed immensely to the analysis of spoken discourse by examining aspects of conversational style, gender, frames, poetic features, narratives, and argument. Her primary focus has been on social interaction, and more recently on gender and family communication. Besides her academic success, Tannen has reached out to the general public, writing linguistic books and articles that have attracted media attention and have led to her appearance on American television, radio, and cable shows.

Tannen received an M.A. in English literature from Wayne State University in 1970. However, the 1973 Summer Linguistic Institute in Michigan was pivotal

in her becoming a linguist. As Tannen said in an interview, the Institute's theme of Language and Context, and especially a course taught by Robin Lakoff, captured her heart and her imagination. Tannen was further inspired to earn her Ph.D. in linguistics under Lakoff at the University of California, Berkeley. Two other Berkeley professors played a fundamental role in her development: John Gumperz, and Wallace Chafe, while another influence was Erving Goffman. Work by Gumperz and his students, Maltz and Borker, on crosscultural communication, was the fundamental block on which Tannen built her theory of gender interaction as crosscultural communication, published in her highly acclaimed book, *You just don't understand: women and men in conversation* (1990). Chafe and Goffman influenced her work on schemata, frames, and footing, theories on which she built and expanded in her publications (1993a, 1994a) that focus on social interaction. Upon her graduation in 1979, Deborah Tannen was hired at

Georgetown University, where she is one of only four professors holding the distinguished rank of University Professor. In addition, she has been a fellow at the Center for Advanced Study in the Behavioral Sciences in Stanford, California, and the Institute for Advanced Study in Princeton, New Jersey.

Tannen has been a prolific scholar and has published 19 books and over 100 academic articles. Several of her books have received numerous prestigious awards and have become *New York Times* best sellers. She has received grants from the National Science Foundation, National Endowment of the Humanities, and more recently from the Sloan Foundation for a project that examines conflict and parental identities at work and at home of middle-class, dual-career couples. In addition, she is the associate editor of *Language in Society* and serves on the editorial boards of many other linguistics journals.

In addition to her immense linguistic contributions, Tannen has published poetry, short stories, and personal essays. She has also written two plays: 'Sisters' and 'An Act of Devotion,' which was included in *The best American short plays: 1993–1994*.

Tannen exemplifies the linguist who feels that academic knowledge is not and should not be the privilege of the few. In 2005, she received the prestigious Linguistic Society of America award for 'Linguistics, language, and the public.' She has popularized many aspects of sociolinguistics and has raised the public's awareness of the importance of linguistics in personal relationships and the workplace.

Telephone Talk

T-S Pavlidou, Aristotle University of Thessaloniki, Thessaloniki, Greece

© 2006 Elsevier Ltd. All rights reserved.

During its approximately 130-year lifetime, the telephone has become an indispensable element of everyday life in most parts of the world, connecting people

who for social and practical reasons are not in auditory reach. Through this medium a 'distinctive and recognizable genre' (Schegloff, 1993: 4548) of talk-in-interaction has developed, namely telephone conversation. Undoubtedly, it is Conversation Analysis (CA) that is to be credited for having made telephone calls an object worthy of linguistic inquiry (*see Conversation Analysis*). Although there had been some

interest in telephone conversation before (see Schegloff, 1993, for references), it was through Sacks and the subsequent conversation analytic approach that telephone calls came to feature on the linguistic stage. And yet Sacks' interest in telephone calls was sociologically guided, as indicated in his often-quoted phrase, "We can read the world out of the phone conversation as well as we can read it out of anything else we're doing" (Sacks, 1992, V. 2: 548) (*see Sacks, Harvey*). What, however, made telephone calls more appealing for this ethnomethodologically grounded type of sociological investigation than other sources of naturally recorded data was that telephone calls stood up to a number of fundamental (theoretical and methodological) imperatives of CA; most notably, telephone data, through their constitutive lack of visual information for the participants involved, allowed the possibility of *-emic* analyses of the interaction, i.e., the analyst had at his/her disposal the same kind and amount of information that was available to the participants themselves in the interaction. Coupled with additional features, some shared by other types of naturally data recordings (e.g., that they can be subjected to scrutiny as often and by as many analysts as one wishes), others being incidental to the specific sociohistorical setting of that research (e.g., that certain U.S. institutions, such as emergency centers, independently made recordings of incoming calls), telephone talk came to play a pivotal role in the conversational analytic approach.

In a series of very influential papers (e.g., Schegloff, 1968, 1986, Schegloff and Sacks, 1973), powerful analyses were provided and the sequential organization of talk in the opening and closing sections of telephone calls was meticulously established. Openings, it was propounded, comprise four core sequences: (a) summons-answer: the telephone rings and the person called picks up the phone and responds to the calling signal, initiating a working channel of communication and displaying availability; (b) identification/recognition: the identities of caller and answerer are ensured through self-identification or other recognition; (c) exchange of greetings; and (d) exchange of tokens of phatic communion (how-are-yous and responses). Closings, on the other hand, were shown to consist of two core sequences: (a) offering to close (preclosing) and accepting to do so; and (b) exchange of farewells, provided that the preclosing is positioned at "the analyzable end of a topic" (Schegloff and Sacks, 1973: 305). As has been variously stressed, 'canonicity' in this framework does not imply that all calls (not even most calls) unfold in the prototypical way. But variation on the basic format was handled primarily as a means toward unraveling the sequential organization of telephone conversation,

either by demonstrably showing it to be a result of structural requirements or by helping in modifying hypotheses about the underlying patterns. When the CA studies on telephone calls got gradually to be known (outside the United States or the CA community), however, variation was also approached from a different angle: to what extent are the CA findings independent of the fact that the data, i.e., American English telephone talk, come from a particular culture only?

In the first two decades after Schegloff's seminal work on openings in the late 1960s, research on telephone calls outside (as well as within) the CA paradigm was not in abundance, and the sporadic studies challenging the CA findings on openings were flawed at least in that they did not rely on recorded telephone calls. By the beginning of the 1990s at the latest, however, the topic of variation was explicitly taken up by a CA proponent, Robert Hopper, most prominently in a book devoted to telephone conversation and focusing, in particular, on openings: "A culture's telephone customs display tiny oft-repeated imprints of community ethos. Ask any traveler, immigrant, or ethnographer about telephone conversations in countries outside the USA. You will hear about differences" (Hopper, 1992: 85). Apart from the late Hopper and his associates, an increasing number of researchers, using recorded data, have been reporting differences, along with similarities, in telephone calls around the world (for references, see Luke and Pavlidou, 2002a). The lion's share of this research deals with openings, whereas to date only a small number of studies on closings is available. One of the reasons for this division of labor is presumably the complexity of closings, which have to take into account all the preceding talk in the phone call and at the same time face the risk of being redefined as yet another stretch of conversation before ultimately ending the call.

In research on telephone calls in languages other than English, a topic that has inevitably attracted attention has been the language specific options and the way that these are exploited in the accomplishment of the phone call. For example, Park (2002), in her study of Japanese and Korean openings, has demonstrated that the contrastive connectives *kedo* (Japanese) and *nuntey* (Korean), when used in self-identifications, signal that the reason for calling is of immediate concern and give the call a business-like tone. In addition to the language specific means, the particular forms in which the core sequences are realized in different linguistic communities have been explored. Houtkoop-Steenstra (1991), for example, has shown that in Dutch openings the answer to the summons is accomplished through

self-identification by name, instead of using something similar to *hello*; moreover, it has been suggested that self-identification is the preferred mode in the Netherlands over other-recognition in the United States – a preference also encountered in other Northern European countries as contrasted to, e.g., Greece. A further issue concerns the relative prominence of the individual components of the canonical opening: although the summons–answer sequence is, by its nature, an obligatory constituent of openings, the greetings or how-are-you sequences seem to get varying relevance across cultures, effecting, among other things, reductions or extensions of the opening. Greetings, for example, have been found to be an integral component of Swedish openings (Lindström, 1994) but dispensable in Greek ones (Sifianou, 2002); phatic utterances of the how-are-you type, by contrast, were shown to be prominent in Greek openings (a point also stressed for Chinese openings [Sun, 2004]), but much less so in German ones (Pavlidou, 1994). This foregrounding of the interactional aspects of communication has been multifariously highlighted, e.g., in terms of the recipients' social status as in *taarof* (ritual politeness) in Persian openings (Taleghani-Nikazm, 2002) or in terms of playfulness and humor (see, e.g., Antonopoulou and Sifianou, 2003, for Greek openings); it also has been shown to affect the organization of closings (for Ecuadorian Spanish, see Placencia, 1997; for Greek, see, e.g., Pavlidou, 1997, 2002).

In contrast to Hopper, who – retaining an intrinsic-to-message view of variation (1992: 72) – claimed that despite divergencies the canonical opening still holds across cultures, other researchers challenge such a “universalist” position. This tension may be resolved if, following ten Have's (2002) proposal, emphasis is given to a functional rather than the structural perspective, which has been more prominent in CA. Of greater consequence, however, seems to be the fact that research on telephone talk has not always been guided by the same motivations and aims as CA, some of it having been called “contrastive cultural analysis”; according to Schegloff (2002), the latter presupposes a within-culture analysis that is grounded in the details of the data and establishes its convergence with the participants' understandings. What is at stake, then, is the transfer of analytical tools developed within one paradigm to a different one without warranting the epistemological prerequisites that necessitated these tools in the first place. Even so, research on telephone talk has occasioned a growing body of naturally recorded data from different linguistic communities and spawned a number of analyses that have proven to be pertinent for areas such as, e.g., foreign language teaching,

inasmuch as telephone talk appears to be a sensitive area in intercultural encounters.

Although certain fundamental features of the phone call have basically remained the same (dyadic nature, lack of visual information), the technical apparatus involved has undergone considerable changes over the years (cordless phones, answering machines, automatic number identification, caller's categorization/identification through ringing melodies, etc.), some of which, like caller identification, have direct effects on the structure of the call. Undoubtedly, the most dramatic innovation, encompassing a number of the features just mentioned, has been mobile telephony. Whereas systematic work on the impact of this technology on society is already available, research on the structure of mobile talk based on recorded data is only beginning, so that claims about changes in the organization of conversation (not to mention variations on expectedly different canonical patterns) effected through the transformation of the medium cannot yet be substantiated. Mobile telephony has contested, at least quantitatively, the traditional mode of calling: reports on the spread of mobiles indicate a ‘penetration’ [*sic*] of over 80% for local markets as different as Hong Kong (cf. Bodomo, 2002) and most West European countries (The Netsize Guide, 2004). By contrast, telephony as a whole seems to have gained impetus and consolidated its place among communication technologies, a place that would otherwise have been most seriously threatened by, e.g., e-mailing.

Communication Through Text and Discourse

People use language to communicate. Language users communicate through discourse. Sometimes, utterances of one word ('John!' 'Okay.' 'Stop!') or one sentence ('I declare the games opened') suffice to get the message across, but usually language users communicate through a connected sequence of minimally two utterances, i.e., discourse. The importance of the discourse level for the study of language and linguistics can hardly be overestimated: "Discourse is what makes us human" (Graesser *et al.*, 1997). It is not surprising, therefore, that the study of text and discourse has become an increasingly important area over the last decades, both in linguistics and psychology.

The term 'discourse' is used as the more general term to refer to both spoken and written language. The term 'text' is generally used to refer to written language. This article focuses on text. Although spoken and written discourse have crucial characteristics in common, the linguistic traditions of the study

of written and spoken discourse are very different. 'Monological texts' are traditionally studied in areas such as stylistics, text linguistics, and psycholinguistics, often based on rather specific linguistic analyses and regularly using a quantitative methodology. By contrast, 'dialogical discourse' has long been the arena of conversation analysis and sociolinguistics, often focused on qualitative interpretations of individual conversations in context. Over the last 10 years, this situation has begun to change. With the growing availability of spoken corpora and the growing insight that the study of spoken and written discourse should be related because they complement each other (Chafe, 1994), the linguistic study of discourse is becoming less and less restricted to one medium. See, for instance, the overview by Ford *et al.* (2001), who relate linguistic subdisciplines such as grammar and the study of conversation.

A text is more than a random set of utterances: it shows connectedness. A central objective of linguists working on the text level is to characterize this connectedness. Linguists have traditionally approached this problem by looking at overt linguistic elements and structures, thereby characterizing it in terms of cohesion (Halliday and Hasan, 1976). By this view, connectedness is localized in the text itself because of explicit linguistic clues, such as pronouns referring to

earlier mentioned subjects (cohesion type: *reference*), e.g., *he* refers to *bird-watcher* in (1); or conjunctions, such as *because* in (2) (cohesion type: *conjunction*), which express a causal relation.

- (1) The bird-watcher had a great day. He observed a kingfisher and a group of 70 cranes.
- (2) The bird-watcher had a great day because he observed a kingfisher and a group of 70 cranes.
- (3) The bird-watcher had a great day. A kingfisher and a group of 70 cranes were in the area.

Influential as the cohesion approach has been, the interdisciplinary field of text linguistics and discourse studies is nowadays dominated by the ‘coherence’ approach: the connectedness of text is considered a characteristic of the mental representation rather than of the text itself. The main reason is probably that a sequence of sentences like (1) or (2) is still interpreted as a perfectly normal piece of text if the cohesive elements of reference and conjunction are absent, as in (3). Hence, the connectedness is not dependent on these overt markers. This does not imply, however, that the linguistic elements signaling text coherence are unimportant.

Although coherence phenomena are of a cognitive nature, their reconstruction is often based on linguistic signals in the text itself. These linguistic expressions are considered ‘processing instructions’ to language users. For instance, referential expressions, such as pronouns and demonstratives, are used in such a way that interpreters can systematically recover the referential coherence (see **Accessibility Theory** and **Discourse Anaphora**). Similarly, connectives (*because*, *however*) and (other) lexical markers of relations, such as cue phrases (*On the one hand*, *on the other hand*) and signaling phrases (*The problem is ... A solution might be ...*), make the meaning relations between text segments explicit. In recent years, the relationship between the linguistic surface code, on the one hand, and aspects of the text representation, on the other hand, has become a crucial research issue in the interdisciplinary field of text linguistics and discourse studies (cf. Gernsbacher and Givón, 1995; Sanders and Spooren, 2001; Graesser *et al.*, 2003).

Text

It follows from the discussion above that, in this article, we consider a text to be a monological stretch of written language that shows coherence. The term ‘text’ derives from the Latin verb *texere* ‘to weave’ (hence the resemblance between the words ‘text’ and ‘textile’). But what is it that makes a text a text? This question has been at the center of attention of

the fields of discourse studies and text linguistics, especially since the 1970s.

Meaning Rather than Form

In the area of syntax – ‘sentence analysis’ – the principled discussion on the question of whether syntax is an autonomous and purely formal level of representation is still going on, especially with the recent rise of cognitive linguistics (cf. Langacker, 1986; Jackendoff, 1996). At the discourse level such a discussion is nowadays absent. In the pioneering years of text linguistics, scholars like van Dijk (1972) and Petöfi and Rieser (1973) attempted to describe texts as a string of sentences within the framework of generative grammar. Analogous to the way in which sentence grammars described sentences in terms of their constituents, texts were seen as constituted by sentences. In generative grammar, a sentence is the result of rewriting rules of the form: $S \rightarrow NP + VP$.

In ‘text grammars,’ a text was regarded as consisting of sentences: $T \rightarrow S_1 \dots S_n$. Similarly, the top of hierarchical text representations was formed by a T (for ‘text’), analogous to the S for sentence in generative sentence representations. In psychology, so-called ‘story grammars’ were developed in the late 1970s (Thorndyke, 1977; Rumelhart, 1977). According to such representations, a ‘story’ consists of a setting (“Once upon a time, there was a little girl who lived in the woods with her parents. She was called Little Red Riding Hood.”) and an ‘episode’ (“One day, her mother asked her to bring some food to grandmother ...”) and, with the help of the same type of rewriting rules, episodes can in turn be represented as a combination of an ‘event’ (“Why do you have such a big mouth? she asked.”) and a ‘reaction’ (“The wolf jumped out of bed and ate her.”):

Story \rightarrow setting + episode

Episode \rightarrow event + reaction

Several scholars have argued that the analogy with sentence grammar is not convincing, among them Brown and Yule (1983) and Wilensky (1983):

... while our intuition of ‘sentencehood’ is a clearly linguistic notion, our intuition of ‘storiness’ most certainly is not [...]. the notion of ‘Story’ refers to actions, events, goals, or other mental or conceptual objects. In other words, our intuitions about stories are closer to our intuitions about the meanings of sentences than they are about they are about sentences themselves (Wilensky, 1983: 580).

And indeed, ever since Halliday and Hasan (1976), Hobbs (1979), and van Dijk (1977), it is widely accepted that purely formal or syntactic principles play

a far smaller role at the discourse level. It is hard, for instance, to make much sense of the idea of a structurally ‘well-formed’ but semantically anomalous text. There is a consensus that the well-formedness of a discourse is primarily to do with its meaning – more specifically, with the question of whether the meanings of its component segments can be related together to form a coherent message.

What Makes a Text a Text?

What, then, are the crucial characteristics of text? At present, the dominant stance is that ‘coherence’ explains best the connectedness shown by texts. Coherence is considered a mental phenomenon; it is not an inherent property of a text under consideration. Language users establish coherence by relating the different information units in the text.

Generally speaking, there are two respects in which texts can cohere (Sanders and Spooren, 2001):

- ‘Referential coherence’: smaller linguistic units (often nominal groups) may relate to the same mental referent throughout the text (*see also Discourse Anaphora*); or
- ‘Relational coherence’: text segments (most often conceived of as clauses) are connected by coherence relations, such as cause-consequence, between them.

Both coherence phenomena under consideration – referential and relational – have clear linguistic indicators that can be taken as processing instructions. For referential coherence, these are anaphoric devices such as pronouns, and for relational coherence these are connectives and (other) lexical markers of relations.

Ever since the seminal work of linguists such as Chafe (1976) and Prince (1981), both functional and cognitive linguists have argued that the grammar of referential coherence can be shown to play an important role in the mental operations of connecting incoming information to the existing mental representations. For instance, referent NPs are identified as either those that will be important and topical, or as those that will be unimportant and nontopical. Hence, topical referents are persistent in the mental representation of subsequent discourse, whereas the nontopical ones are nonpersistent. In several publications, Ariel (1988, 2001) argued that regularities in grammatical coding should indeed be understood to guide processing. She studied the distribution of anaphoric devices and suggested that zero anaphora and unstressed pronouns cooccur with high ‘accessibility’ of referents, whereas stressed pronouns and full lexical nouns signal low accessibility. This

cooccurrence can easily be understood in terms of cognitive processes of activation: high-accessibility markers signal the **default** choice of continued activation of the current topical referent. Low-accessibility anaphoric devices, such as full NPs or indefinite articles, signal the terminated activation of the current topical referent and the activation of another topic (*see Accessibility Theory*).

‘Centering theory’ (see Walker *et al.*, 1998 for an overview) makes explicit and precise predictions about the referent that is ‘in focus’ at a certain moment in a discourse. It even predicts that the degree of text coherence is determined by the extent to which it conforms to ‘centering constraints.’ Given a clause in which referential antecedents are presented, centering theory predicts the likelihood that an antecedent will be a central referent – which is ‘in focus’ – in the next clause. The salience of a discourse entity is determined by a combination of syntactic, semantic, and pragmatic factors, such as grammatical role (subject or not), expression type (zero, pronoun, or NP), and discourse topic-hood. Several processing studies have demonstrated the ‘psychological reality’ of linguistic indicators of referential coherence (see Garrod and Sanford, 1994, and Sanford and Garrod, 1994, for an overview; *see also Discourse Processing*).

We now turn to (signals of) ‘relational coherence.’ ‘Coherence relations’ are often taken to account for the connectedness in readers’ cognitive text representation (cf. Hobbs, 1979; Sanders *et al.*, 1992). They are also termed ‘rhetorical relations’ (Mann and Thompson, 1988; *see Rhetorical Structure Theory*) or ‘clause relations’. ‘Coherence relations’ are meaning relations connecting, at a minimum, two text segments. A defining characteristic for these relations is that the interpretation of the related segments needs to provide more information than is provided by the sum of the segments taken in isolation (Sanders *et al.*, 1992). Examples are relations like ‘cause-consequence,’ ‘list,’ and ‘problem-solution.’ These relations are conceptual and they can, but need not, be made explicit by linguistic markers, so-called connectives (*because, so, however, although*) and lexical cue phrases (*for that reason, as a result, on the other hand*).

In the last decade, much research in relation semantics and pragmatics has focused on the question of how to taxonomize or classify the set of coherence relations (Hovy, 1990; Knott and Dale, 1994; Pander Maat, 1998; Redeker, 1990; Sanders, 1997). The main reason for this interest is the cognitive interpretation of coherence relations: if they are to be considered as cognitive mechanisms underlying discourse interpretation, it is attractive to find out which more general principles are involved in relation

interpretation. While work on the hierarchical classification of discourse relations goes back at least as far as Grimes (1975) and Halliday and Hasan (1976), the idea that a small number of reasonably orthogonal primitives is responsible for the differences amongst coherence relations is more recent. Sanders *et al.* (1992) defined the ‘relations among the relations,’ relying on the intuition that some coherence relations are more alike than others, and that the set of relations can be organized in terms of more primitive notions, such as polarity and causality. Several types of evidence in favor of such an organization were produced, varying from experiments in which text analysts judged relations (Sanders *et al.*, 1992, 1993; Sanders, 1997), to research on the acquisition order of connectives (Evers-Vermeul, 2005) and processing studies indicating how different coherence relations result in different representations (Sanders and Noordman, 2000). In such an account of coherence, connectives and other lexical signals are seen as ‘processing instructors.’ And indeed, experimental studies on the role of connectives and signaling phrases show that these linguistic signals affect the construction of the text representation (cf. Millis and Just, 1994; Noordman and Vonk, 1997).

In sum, it can be concluded that there is compelling evidence, from both linguistic and psycholinguistic studies, in favor of the view that referential and relational coherence are crucial principles, which make a set of sentences a text.

Text Analysis

Now that we have an idea of what a text is, we can define ‘text analysis’ as the systematic dissection of a textual unity in its constituent parts and the study of those parts in relation to each other. By consequence, text analysis focuses on the linguistic elements present in the text. Texts may be analyzed with different aims and from several perspectives.

A first text-analytic research goal is of a theoretical nature. It concerns the further development of linguistic theory at the discourse level: how are texts structured? There are now several well-established theories that propose mechanisms by which the meaning of individual sentences can be constructed, but the situation with entire texts is different. Text analysis is of crucial importance to the further development of text linguistics.

A second aim is to provide insight into the cognitive processes of reading and writing, or in the text representation that language users have of a text. In reading research, the role of text structure is an important research topic in which text analyses

are used to model both the text structure and the representation that readers make of it (see previous paragraph). In writing research, the role of text analysis has received less attention for a long time, even though Bereiter and Scardamalia (1987) argued for the interaction between psychological models and text linguistic research. They pointed to a deficiency in studies of writing and argued that text analysis had a large role to play in discovering the implicit rules of composition.

A third aim is of a computational linguistic nature: the development of computational models of automatic summarization, text generation, and interpretation. Here, the analysis of natural texts should provide the rule system to arrive at such computational models. Although some theories and models discussed in the sections to follow were explicitly developed in the context of such a computational enterprise (such as **Rhetorical Structure Theory**), computational text analyses are not discussed here.

A fourth aim is the evaluation of text quality in the context of written composition and document design. A text analysis can provide the basis for a comparison of similar texts, enabling researchers to compare the writing ability of the authors (Cooper, 1983). In document design, text analysis can predict areas where readers may have difficulties and where revision is imperative. It is also used to investigate the relationship between text structure and the successful layout of various documents, even multimodal ones (Delin and Bateman, 2002).

From what perspectives do text analysts try to catch the ‘meaning’ in text? A first division is that between content-oriented and structure-oriented approaches. ‘Content-oriented’ approaches to text analysis uncover what an individual text is ‘about,’ either by starting from the smallest building blocks (propositions) or by characterizing texts on a more global level: the topics and subtopics that are covered. ‘Structure-oriented’ approaches uncover the meaning relations between the textual building blocks, such as causal, contrastive, and additive relations, but also referential relations. Some approaches provide analytic models that allow for a hierarchical representation representing the whole text in such terms.

Content-Oriented Approaches

Micro- and Macrostructure In the context of a psychological model of text processing, Van Dijk and Kintsch (1983) distinguished between three aspects of text representation: ‘microstructure,’ ‘macrostructure,’ and ‘superstructure’. Superstructures – representing the global structure that is characteristic of a text type – will be discussed in the section on

structure-oriented approaches. Micro- and macro-structure concern the **content** of a text. The basic building blocks of these representations are ‘propositions,’ i.e., a unit of meaning that consists of a predicate and connected arguments. For instance, the proposition underlying sentence (4) would be (4’), where *see* is the predicate and *he* and *kingfisher* are the arguments.

(4) he sees a kingfisher

(4’) (see (he, kingfisher))

The microstructure is a network of propositions like these that represents the textual information in a bottom-up fashion, sentence by sentence. Building on earlier work, van Dijk and Kintsch (1983) presented an influential model of text comprehension, which predicted the information recalled best by readers. For the purpose of text analysis, it is important to focus on another component of the Van Dijk and Kintsch model: macrostructure. On the basis of the microstructure or ‘text base,’ a macrostructure can be built – an abstract representation of the global meaning structure that would reflect the gist of the text. This is achieved by applying macro-rules to the detailed meaning representation of the microstructure. ‘Deletion,’ ‘generalization,’ and ‘construction’ are such macrorules, which produce macropropositions: the main ideas in the text (see especially van Dijk, 1980). This idea of producing the macrostructure on the basis of the details of the microstructure is certainly appealing. The results of some experimental processing studies seem to show that macrostructures can predict recall and summarization results: Propositions present in the macrostructure are remembered better than propositions that are ‘only’ present in the microstructure (Graesser, 1981). Arguably, the theoretical and empirical status of this part of the van Dijk and Kintsch theory is less clear than the microstructure part. This was probably a result of the fact that macrorules were underspecified. In addition, it is not always easy to identify linguistic signals of macropropositions at the surface level of the text, even though titles, headings, abstracts, and topical sentences are mentioned as signalling macropropositional ideas. In recent years, Kintsch (1998) and others have argued that macrostructures can be derived from texts by using ‘latent semantic analysis’ Here, the meaning of sentences is represented by a vector in a high-dimensional semantic space. Vectors that relate most to the rest of the text can be identified as macropropositions.

Theme and Thematics ‘Thematics’ is the interdisciplinary study of ‘about-ness’ in text. The notion of

‘theme’ refers to the main idea or topic of the text. For instance, a text can be about a kingfisher or about an ornithologist having a great day. The study of theme has been popular in literary studies. Thanks to the involvement of text linguistics and stylistics, the study of linguistic cues that create thematic meaning has become increasingly important (Louwerse and Van Peer, 2002). For instance, formulations and stylistic figures also emphasize the thematic meaning of a text.

However, regular aspects of formulation, such as the linear order of the information in clauses and sentences, can also contribute to the identification of the theme. A typical linguistic aspect studied in more detail is the way in which the first position in a clause has a special textual status. The terminology is somewhat confusing here, because linguists refer to the information provided in this position with the term ‘theme,’ whereas any information following this local theme is called ‘rheme’. The opening positions of clauses often contain information that guides the reader in constructing a picture of the text as a whole. In linguistics, and especially in systemic functional grammar, sequences of theme–rheme are studied, resulting in patterns of thematic development.

Structure-Oriented Approaches

Most linguistic methods of text analysis focus on the general properties of text structure, abstracting away from the specific content of individual texts. Accounts of text structure usually pay attention to

1. the meaning of the left-right relations between text segments, where the analysis is based on relational and referential coherence; and
2. the hierarchical structure of the text, which accounts for the intuition that the information that is ordered higher in a tree-like representation is more important than the lower information.

Superstructure van Dijk and Kintsch’s (1983) model included micro- and macrostructures, which resulted in a representation of the text content, as was discussed above. The third element in their model is the ‘superstructure,’ which “provides a kind of overall functional syntax for the semantic macrostructures” (van Dijk and Kintsch, 1983: 242). It is the conventional, hierarchical form in which the content of the macrostructure is presented. An example of such a superstructure is that of the type ‘news discourse,’ in which superstructural categories are distinguished, for example, *headlines*, *lead*, *context*, *event*. Superstructural categories are typically of a global nature

in that they organize larger chunks of text rather than consecutive sentences. In addition, a superstructure analysis proceeds top-down: it starts from the highest text level. Superstructures for several other conventional text types were developed, among them the 'Experimental article.' There seems to be a clear parallel here with text type and genre: it would seem logical to expect that stereotypical text types can be characterized in terms of a superstructure (see **Genre and Genre Analysis**). Therefore, a text analysis in terms of superstructures is text type-specific by definition.

Clause Relations, Coherence Relations, and Discourse Patterns By contrast, a text analysis based on clause or coherence relations would be generally applicable, independent of text types. It proceeds bottom-up, starting from consecutive clauses. One common relation is called 'problem-solution' or 'solutionhood'. See examples (5) and (6).

- (5) I'm hungry. Let's go to the Fuji Gardens.
- (6) What if you're having to clean floppy drive heads too often? Ask for Syncom diskettes, with burnished Ectype coating and dust absorbing jacket liners.

Mann and Thompson (1986, 1988) treated solutionhood as simply one of the relations, where others have argued that solutionhood was more complex than that (Grimes, 1975; Hoey, 1983; Sanders *et al.*, 1993): "Both of the plots of fairy tales and the writings of scientists are built on a response pattern. The first part gives a problem and the second the solution" (Grimes, 1975: 211). On the basis of clause relations, more complex structures can be built: a 'discourse pattern' (Hoey, 1983) or a 'response pattern' (Grimes, 1975). Hoey (1983) argued that a recurrent combination of clause relations can organize a substantial text fragment, or even a whole text. See the illustrating example from Hoey (1983: 35):

- (7) (i) I was on sentry duty.
- (ii) I saw the enemy approaching.
- (iii) I opened fire.
- (iv) I beat off the attack.

Hoey provided several paraphrase tests to recognize the clause relations on which the pattern is based: 'instrument-achievement' with '(iii) thereby (iv),' 'by (iii) . . . ing,' and '(iii) by this means (iv)' (Hoey, 1983: 39–41); and 'cause-consequence' 'because (ii), (iii)' and '(ii) therefore (iii)' (Hoey, 1983: 41–42). Paraphrase tests like these are often a great help for inexperienced text analysts, who find it hard to determine the exact relationship expressed between text segments.

This heuristic to identify discourse patterns is an outstanding example of a text-analytic method in the field of clause and coherence relations. The research in this field discussed earlier in this section has probably been more important for the identification of coherence relations and for the theoretical issues discussed earlier (the nature of coherence, taxonomies of relations, the linguistic expression and processing of relations). However, a very important account has not been discussed so far: rhetorical structure theory.

Rhetorical Structure Theory In the 1980s and 1990s, Mann and Thompson (see especially Mann and Thompson, 1988) presented 'rhetorical structure theory' (RST), a functional theory of text organization developed in the context of linguistics and cognitive science (see **Rhetorical Structure Theory**). At the heart of RST are the so-called 'rhetorical relations,' similar to clause or coherence relations, and including relations like 'cause,' 'elaboration,' and 'evidence.' The relations are defined in terms of conditions on the nucleus (the most important segment in a relation), on the satellite (which depends on the nucleus), and their combination, and in terms of the effect on the reader. Relations are identified between adjacent text segments (e.g., clauses) up to the top level of the text. The top level of an RST tree organizes the text as a whole: a relationship that dominates the total text structure.

Rhetorical structure theory has proven to be a very useful analytic tool. One of its benefits is that it allows for a complete analysis of any text type: expository, argumentative, or narrative. The system has been applied to many real-life texts, among them newspaper articles, advertisements, and fundraising letters (Mann and Thompson, 1992). As a rule, an RST analysis starts with an inspection of the **entire** text. The analysis does not proceed in a fixed way; it proceeds bottom-up (from relations between clauses to the level of the text) or top-down (the other way around) or follows both routes (Mann *et al.*, 1992). The analysis results in a hierarchical structure that encompasses the entire text and has a label attached to each of its branches.

Although RST defines rhetorical relations in a fairly exact way, the assignment of a label is ultimately based on observed 'plausibility.' Four general constraints are the guidelines: 'completedness,' 'connectedness,' 'uniqueness,' and 'adjacency' (Mann and Thompson, 1988: 248–249). How the analysis actually proceeds is left to the intuitions of the analyst and is, in the end, a matter of text interpretation. Still, it has been shown that RST can be applied with a reasonable amount of consensus by expert text

analysts (Den Ouden, 2004) and to a certain extent, RST analyses can even be produced automatically (Marcu, 2000).

Procedural Text Analysis Rhetorical structure theory requires a fair amount of text interpretation based on the analysts' overview of the text as a whole. This overview situation may not reflect the way in which writers produce texts. Spontaneously produced texts, especially, are the result of a more incremental process. Sanders and van Wijk (1996) developed 'procedures for incremental structure analysis' (PISA), which incorporates both ideas about written text production and insights from the text analytical literature, especially with respect to hierarchical aspects of text structure. The two texts in example (8) are taken from the PISA corpus. They were written by 12-year-old boys in response to a request to explain who Saint Nicholas is to someone who knows nothing about the subject. The texts are translated from Dutch in a rather literal way, preserving the original punctuation. For the analysis, texts were divided into

segments, roughly corresponding to clauses. The hierarchical structures of the texts in (8a and 8b) are shown in Figures 1 and 2.

(8a) (1) Every year Saint Nicholas comes (2) that is on the 4th of December (3) That day he comes by steamboat (4a) When he arrives in the Netherlands (4) then everyone waves to him (5) At night (5a) when it is pitch-dark (5) Saint Nicholas rides over the roofs with Black Peter (6) and throws lots of presents through the chimney (7) while the children sing a song (7a) such as: Sinterklaas kapoentje . . . (8) Saint Nicholas gives lots of presents (9) but he always gets something in return (10) That is either a carrot for the horse or a bit of water, also for the horse (11) On the fifth of December Saint Nicholas really has his birthday (12) on that day he brings the presents (13) and then he leaves again. (14) He also looks into the red book with the cross on it. (15) There it says whether you have been naughty or not (16a) When Saint Nicholas leaves again (16) the children sing Bye bye Saint Nicholas.

Figure 1 Hierarchical structure of an explanatory text, dominated by a sequence of actions. (Reproduced from Sanders T & van Wijk C (1996). 'PISA – a procedure for analyzing the structure of explanatory texts.' *Text*, 16(1), 91–132 with permission by Elsevier.)

Figure 2 Hierarchical structure of an explanatory text, dominated by referential coherence. (Reproduced from Sanders T & van Wijk C (1996). 'PISA – a procedure for analyzing the structure of explanatory texts.' *Text*, 16(1), 91–132 with permission by Elsevier.)

- (8b) (1) Saint Nicholas is an old man (2) He has a white-grey beard (3) He has a steamboat with a lot of little black men (4) They are called Black Peter (5a) When it is the fifth of December (5) the time has come. (6) The day of Saint Nicholas is a Big Festival. (7) The Peters have a birch. (8) A birch is a bundle of swishing branches. (9) They also have a sack (10) that is a kind of wool and a shape. (11) The children in all villages and towns got ginger-nuts. (12) And ginger nuts are four-sided blocks, with sugar. (13) That is candy (13a) that children like. (14) Well, Saint Nicholas is an old man, with white hair. (15) He wears a red robe. (16) And wears a sort of shirt. (17) He also has a whitish grey. (18) A grey is a horse. (18a) (noble animal) (19) Just now I was talking about a steamboat. (20) A steamboat is a big ship, (21) a steamboat often has got a big funnel (21a) from which the steam comes. (22) The children sing songs on the fifth of December, (23) that is because there is a big feast.

The texts in (8) illustrate two different ways of arranging information in an explanatory text. The first one follows the **temporal order** of events: first he arrives, then, at night, he rides over the roofs. On December 5, he has his birthday and the children get presents. And then he leaves and the children sing to him. By contrast, the writer of the second text solves the problem of explanation by focusing on the topic of the text. He mentions all kinds of **properties** of Saint Nicholas in a rather associative way: He is old, has a white beard, a steamboat, etc.

Clearly, these two texts differ in their global structure. The first one is dominated by an 'action-line,' a temporal sequence of actions, and the second one is dominated by a 'property-line,' a list of characteristics of the topic. Text structures like these may reflect the way in which the writer has organized the information during the production of the text. For example, the first text can be produced by running through episodic memory; the actions or events are mentioned in temporal succession and the text ends with the closing of an episode. The second text, on the other hand, is probably produced by searching semantic memory in an associative way. It resembles brainstorming; it lists information related to the topic, which is potentially relevant to explain it.

In a series of publications, it has been argued that the product of this text-analytical method is cognitively interpretable because it correlates with pause time distribution during writing (Schilperoord, 1996; Sanders and Schilperoord, 2005) and explains writing development (van der Pool, 1995), sentence-combining results, and problems during writing (van Wijk

and Sanders, 1999). The generalizability of an incremental and procedural approach like this is limited; it has specifically been shown to be successful for spontaneously written explanatory texts and judicial letters that were produced without much planning.

Conclusion and Further Research

There are several interesting developments for the research agenda in the years to come. Before we go into detail, a general methodological remark seems in order. Text analyses of corpora of natural language texts have a crucial role to play in text linguistics and discourse studies, because the development of theoretical models of discourse phenomena needs to proceed in interaction with the study of the (sometimes very complex) reality of natural language in use (cf. Emmott, 1997).

Let us now focus on some specific issues that follow from our analysis of the state-of-the-art in the preceding sections. A first important issue is the linguistics/text linguistics interface. There are clear rapprochements between grammarians, (formal) semanticists, and pragmaticists on the one hand and text linguists on the other hand (Sanders and Spooren, 2007). Questions to be asked are: what is the relationship between information structuring at the sentence level and at the discourse level? How do factors such as tense, aspect, and perspective influence discourse connections (Lascarides and Asher, 1993; Oversteegen, 1997)? For instance, discourse segments denoting events that have taken place in the past (*The bird-watcher saw a small blue bird near the river. It was a kingfisher*) will typically be connected by coherence relation of the content type, whereas segments in the present/future, which contain many evaluations or other subjective elements (*Here is that small blue bird again. It must be a kingfisher*), are prototypically connected by epistemic or argumentative relations. This correlation, in turn, should be studied in connection with issues like perspective and subjectivity (Sanders and Redeker, 1996; Pander Maat and Sanders, 2001).

A second obvious issue is the relationship between the principles of relational and referential coherence. Clearly, the two types of principles both provide language users with signals during text interpretation. These signals are taken as instructions for how to construct coherence. Therefore, the principles will operate in parallel, and they will influence each other. The question is: How do they interact? Consider a simple example.

- (9) John congratulated Pete on his excellent play.
 (a) He had scored a goal.
 (b) He scored a goal.

At least two factors are relevant for the solution of the anaphor *he* in (a/b): the aspect of the sentence, and the possible coherence relations that can be inferred between sentences. Part (9a) has perfect tense, and at the discourse level, the interpretation of one coherence relation is obvious – namely the backward causal relation ‘consequence-cause.’ The tense of (9b) is imperfect, and at the discourse level several coherence relations can exist, including ‘temporal sequence’ (of events) and ‘enumeration/list’ (of events in the game). Hence, the resolution of the anaphor-antecedent relation seems to be related to these two factors. In (9a) *he* must refer to Pete; in (9b), both antecedents are possible: John or Pete. How do aspect and the coherence relation interact in the process of anaphor resolution? And: Is the anaphor resolved as a consequence of the interpretation of the coherence relation? Questions like these were already addressed in the seminal work of Hobbs (1979) and recently taken up again in a challenging way by Kehler (2002). Text analysis of natural texts has a large role to play here: How often do ambiguities like these actually show up in text? What are the heuristics apparently used by language users?

A third issue is the further characterization of genres and text types in terms of their text structure. Genre and text type are both frequently used concepts (see **Genre and Genre Analysis**) that are often not defined in articulate text-internal characteristics (see Virtanen, 1992). Now that text-analytic models like RST are available and the theory of different types of coherence relations has matured, it is high time that structural analysis of real-life corpus texts show whether text types differ systematically in their text structure. In a first corpus study (Sanders, 1997), such a correlation was indeed found. ‘Informative texts’ (in which the writer’s goal is to inform the reader about something) were compared to ‘expressive texts’ (in which the writer’s goal is to express his or her feelings and attitudes) and ‘persuasive texts’ (in which the writer’s goal is to persuade the reader of something). It was shown that persuasive texts were indeed dominated by more subjective relations, used by the writer to put forward the argument, whereas encyclopedic texts were shown to be informative because their structure was dominated by more objective relations, in which the writer simply described the content area. The realization of this type of text-analytic work on a larger scale would make notions of text type more concrete, but it also provides an example of the way in which text structural characteristics could be operationalized for the further study of language use, on a par with many stylistic text characteristics.

A fourth and final issue concerns the role of text analysis in text evaluation and document design. Many teachers believe that the best and the worst essays written in class differ in organization. The best one is structured clearly, whereas the worst one is hard to follow. Traditionally, there are few results from research to underpin observations like these. However, this situation has recently improved. For instance, children’s explanatory texts showing continuity might be judged better than texts that show discontinuities (Sanders and van Wijk, 1996; van Wijk and Sanders, 1999). There are at least two cognitive reasons to link structure and judgments about text quality: texts are easier to understand without such discontinuities, and discontinuities often point to a lack of text planning during writing (Sanders and Schilperoord, 2005).

The use of text analysis in document design is particularly promising because it not only appears valuable in the study of ‘classical’ text structure, but it is also a useful basis to investigate the matching of text structure, content, and layout, including visual images (Delin and Bateman, 2002). This type of work shows the way to the text analysis of the 21st century: that of multimodal documents.

Text World Theory

J Gavins, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

'Text World Theory' is an attempt to unify a number of key ideas about human discourse processing under one analytical framework. Its structure is drawn from a range of diverse disciplines, including possible-worlds logic, discourse analysis, cognitive psychology, cognitive linguistics, and stylistics. The original text-world framework was formulated by Paul Werth during the 1990s, primarily in relation to literary fiction (e.g., Werth, 1994, 1995a, 1995b, 1999). More recently, Text World Theory has been further developed and applied to a broad range of both literary and nonliterary discourses (e.g., Gavins, 2000, 2003, 2006; Hidalgo Downing, 2000; Stockwell, 2002). The basic theoretical premise underlying Text World Theory is that human beings understand discourse by constructing mental representations, or 'text worlds', of it in their minds. The practical aim of the theory is to provide an accurate account of human communication processes, in all their cognitive and psychological complexity. This necessarily means investigating both the discourse itself and the context surrounding its production and reception.

Text World Theory approaches this considerable task by splitting human communication into three manageable levels: the 'discourse world,' the 'text

world,' and the 'subworld' (Werth, 1994, 1995a, 1995b, 1999). The first of these levels, the discourse world, deals with the immediate situation surrounding at least one speaker or writer and one or more listeners or readers. These sentient beings are referred to in Text World Theory as the 'participants,' the conscious presence of whom is essential for a discourse world to exist. This is because the discourse world includes not only the participants and the objects and entities that surround them, but all the personal and cultural knowledge that the participants bring with them to a language situation. This knowledge is of central importance to our understanding of human communication, since it has the potential to impact upon both the construction and comprehension of a given discourse. The majority of preceding approaches to discourse study have fought shy of dealing with context, mainly because of the fact that its unwieldy nature at first appears incompatible with rigorous linguistic analysis. Text World Theory, on the other hand, introduces the principle of 'text-drivenness' to provide a manageable route into the systematic examination of context. This principle specifies that, from the vast store of personal knowledge and experience available to the participants, it is the **text** produced in the discourse world that determines which areas are needed to process and understand the discourse at hand. When discussing recent film releases with friends, for example, we need only

activate this area of our knowledge. Our experiences of cake decoration or crossing the road remain redundant, unless specifically referred to in the course of the conversation.

Every time a new act of communication occurs, a new and unique discourse world comes into being, the contents and structure of which will depend greatly on the nature of the communication in question. In face-to-face communication, for example, the participants share the same physical space and are able to refer directly to objects and entities in the immediate surroundings. Other nonlinguistic factors, such as body language and intonation, will also play a part in the structure of the discourse and the relative ease with which it is comprehended. There are a number of situations in which the discourse world will be split between two, or even more, spatial and temporal locations. The participants in telephone communication or internet chat room conversation, for example, normally share a temporal location (except in the case of telephone answering machine messages) but not a spatial one. The discourse worlds of written communication, on the other hand, are often split both spatially and temporally, sometimes over many thousands of miles and many hundreds of years. Some discourse worlds (the reading of a novel, for example) may continue over many months, in a variety of different locations, while others (a passing nod on a crowded train) may be fleeting and minimally detailed. In each case, however, the context surrounding the participants, whether shared or separate, is of paramount importance in the processing of the discourse. Consider, for example, the differing experiences of reading *Cædmon's hymn* from a projector screen in a lecture hall in New York and reading it from a carved stone crucifix on a cliff top in Whitby, England.

As the participants in the discourse world communicate with one another, they construct mental representations of the discourse in their minds, in which the language being produced can be conceptualized and understood. These mental representations are known as 'text worlds.' The deictic and referential expressions included within a text establish the spatial and temporal boundaries of the text world and specify whether any entities or objects are present. These details, known as the 'world-building' elements of the text, can be seen to form a kind of static conceptual background against which certain activities and descriptions may be played out. These activities and descriptions are known as the 'function-advancing' elements of the text world, the precise nature of which will vary depending on the type of text involved. In narrative texts, for example, actions and events are often in abundance, the function of

which is to propel the narrative forward. The function-advancing elements of an instructive text, on the other hand, are likely to include a greater number of imperatives, and so on.

Once a text world has been created, any number of departures from its initial world-building parameters may occur during the discourse process. These departures cause new worlds to be created in the minds of the participants. They constitute the third and final layer of Text World Theory and are known as 'sub-worlds.' A subworld may be created by one of the participants at the discourse-world level. In such cases, the participants are free, particularly in face-to-face communication, to question one another's statements and to clarify any aspect of the discourse they do not understand. When entities at the text world level (referred to as 'characters' in Text World Theory) communicate, however, the reliability of the worlds they create cannot be assessed according to the same criteria as those produced in the discourse world. In Text World Theory terms, worlds created by the participants are 'participant-accessible,' while worlds created by characters are only 'character-accessible.' This logical distinction is one basically drawn between the different ways the participants process worlds created at the different conceptual levels of the framework, and explains why, in some cases, judgment may be reserved on the dependability of the contents of a particular world.

Sub-worlds are created for a variety of reasons but generally fall into one of two broad categories. 'World-switches' (Gavins, 2003, 2006) occur when the temporal or spatial parameters of the text world change. The text may flash backward or forward to a different time zone, or it may switch the spatial location of the world as a concurrent scene is referred to or described. Changes in the temporal parameters of a world often occur in conjunction with a change in the spatial parameters as well. Instances of direct speech and direct thought representation may also cause a world-switch, as present-tense discourse is injected into a past-tense narrative. In each case, a new world is created appropriate to the new time or scene.

Slightly more complex are 'modal worlds' (Gavins, 2003, 2006), which occur whenever some form of modalization is used in a discourse. Modal expressions are usually separated into three categories: 'deontic,' 'boulomaic,' and 'epistemic.' In Text World Theory, the use of each of these creates a corresponding modal world. Deontic modal worlds are created whenever a degree of obligation is attached to a proposition. For example, if I say that someone '**must** keep off the grass' or that they '**should** do the washing up,' a new world is created in which

the activity of 'keeping off the grass' or 'doing the washing up' is taking place. Although a participant or character may be expressing their **attitude** to such propositions in the discourse world or the text world, the activities themselves are, as yet, unrealized. A separate, modal world must therefore be created for us to conceptualize both the activity and the world-creator's attitude toward it. Boulomaic modal worlds operate in a similar manner. Whenever a speaker or writer expresses a degree of desire, a separate modal world is created in which the proposition in question can be conceptualized. For example, if I say 'I **wish** I had more days in the week,' the boulomaic modal verb 'wish' causes a new world in which 'more days in the week' exist. This situation is, of course, unrealized and therefore remains in a mental space separate from the main discourse.

Epistemic modal worlds allow us to conceptualize expressions of remoteness in discourse and can occur for a number of different reasons. Instances of indirect speech, indirect thought, and free indirect discourse all filter a text, however fleetingly, through a new perspective. This perspective thus creates a new world in which the resulting epistemic distance from the initial speaker or writer can be fully conceptualized. Focalized narration in written discourse has a similar effect, since readers are aware throughout that their only access to the text world is through the mind of a character who may or may not be participating in the unfolding events. The character-accessibility of such modal worlds is frequently manipulated by literary authors to create disorienting or deliberately misleading narrative effects. Hypotheticals also cause modal worlds to be created, since they necessarily depict unrealized events at some epistemic distance from the text world. Finally, conditional constructions require separate worlds for us to conceptualize the remote situations they describe. In the sentence 'If you see Paul, tell him he owes me a fiver,' for example, the 'if' marker signals the construction of a remote situation in which the addressee comes into contact with Paul. The 'tell him he owes me a fiver'

section of the conditional can be seen to advance this modal world further by providing added detail of the possible future events concerned.

The main application of Text World Theory to date has been to literary discourse (e.g., Gavins, 2000, 2003; Hidalgo Downing, 2000; Stockwell, 2002; Werth, 1994, 1995a, 1995b, 1999), where it provides a systematic framework for investigation of the conceptual structures involved in the processing of certain poetic and narrative devices. Increasingly, however, Text World Theorists are finding new and fruitful ground in nonliterary discourses as diverse as family arguments, verbal directions, media discourse, and Web authoring (Gavins, 2006).

In the late 19th and early 20th century, there were two major attempts at overcoming the Aristotelian

articulation of the clause (or 'judgment') in subject and predicate: one by Gottlob Frege (see **Frege, Friedrich Ludwig Gottlob**), who did away with the distinction altogether, and one by Franz von Brentano and Anton Marty, who restricted the traditional subject–predicate articulation to what they called 'categorical judgments,' as opposed to 'thetic judgments,'

which do not involve an act of predication about some ‘psychological subject’ but attribute something to a situation as a whole.

This suggestion was later taken up by the Czech linguist Vilém Mathesius (1929), who saw the sentence as a communicative utterance by which the speaker assumes some active attitude to some fact or group of facts (1983: 124). In declarative sentences, this active attitude is assertion. An assertion can either be the simple presentation of an event or action (like in Czech *byla tma* ‘it was dark’; *thetic*) or a predicative statement about a theme (*and the king had a beautiful daughter*; *categorical*).

It was not until 1972 that the U.S.-Japanese linguist Sige-Yuki Kuroda rediscovered the Brentano-Marty proposal. He argued that the much discussed difference between the Japanese ‘subject’ particle *ga* and the ‘topic’ particle *wa* actually reflected a distinction between two judgment types, viz., the categorical and the *thetic*. At the time of its publication, however, Kuroda’s paper did not have too much impact, as another U.S.-Japanese scholar, the Harvard linguist Susumo Kuno (1972), had just proposed a different explanation of the same phenomenon in terms of information structure: the *ga*-clauses in question were ‘neutral descriptions,’ which contained all new information, while *wa*-clauses were about some (given or contrasted) topic. This proposal tailed in with a long-standing discussion about ‘accented subjects’ in English (see Bolinger, 1954; Fuchs, 1980) and similar phenomena.

A number of scholars of Romance languages (such as Vattuone (1975) on Genoese Italian and Ulrich (1985) on Romanian) maintained that the word order verb–subject (VS, in contrast to subject–verb, SV) in these languages codes *thetic* judgments. (Similar observations have been made for Hungarian, Russian, Bulgarian, and Modern Greek.) This claim was taken up by Hans-Jürgen Sasse in 1987. His point is that the *thetic/categorical* distinction (which he relates to the sentential communication perspective) is independent of the information-structure phenomena described by Kuno (which Sasse associates with discourse–pragmatic presuppositions). (see **Pragmatics: Overview; Discourse, Foucauldian Approach.**)

If *thetic* judgments were simply ‘neutral description’ sentences, they would be the appropriate answer to questions (such as ‘*What happened?*’) that do not introduce any discourse-pragmatically presupposed material (see **Pragmatic Presupposition**). But while such questions are a valid diagnostic for neutral descriptions (and ‘all-new’ sentences), they fail as a diagnostic for *thetic* judgments. In answering, the speaker still has a choice between, for example, VS

and SV forms in Italian: he or she can either focus on the situation as a whole and make a statement about this, or choose a topic as a predication base and predicate something about this topic. This topic would then be new in the given situation; the resulting sentence is a categorical, all-new sentence.

Grammatical structure can be said to have two core articulations: a semantic articulation as predication and a topicality articulation as judgment. But there is also another, pragmatic articulation, that of given vs. new (Haberland and Nedergaard Thomsen, 1993: 177). Whether the *thetic/categorical* distinction is grammatically relevant depends on whether a language emphasizes topicality articulation (situational pragmatics) rather than information structure (discourse pragmatics). In other words, the question is whether the available syntactic means are more suited for expressing a *thetic/categorical* than an information structure-based distinction. So far, the following syntactic phenomena have been suggested as realizing the *thetic/categorical* distinction:

Noun incorporation:

Boni (Sasse, 1984)

Verb–Subject order:

Genoese Italian (Vattuone, 1975)

Romanian (Ulrich, 1985)

Modern Greek (Sasse, 1987)

Swahili (Sasse, 1987)

Split structures:

French (Ulrich, 1985; Sasse, 1987)

Dummy subjects:

Danish (*der*) (Heltoft, 1993)

Intonation features (‘accented subjects’):

English (Sasse, 1987)

German (Sasse, 1984)

Morphological marking:

Japanese: *wa* versus *ga* (Kuroda, 1972;
Shibatani, 1991)

Lambrecht (1987, 1994) has proposed a more fine-grained typology of focus that aims at capturing both the phenomena analyzed by the information-structure approach (as outlined by Kuno) and the *thetic/categorical* approach à la Kuroda, Sasse, and others (for a discussion, see Van Valin, 1990). In Lambrecht’s approach, *thetic* judgments are cases of sentence focus.

A very critical discussion of the issue can be found in Wehr (2000).

Topic and Comment

Definitional Problems and History of the Terms

There are few terms and concepts in linguistics as problematic as Topic and Comment; few have had such a wide range of different applications that affect such fields as grammar, typology, pragmatics, and sociolinguistics. Moreover, few terms and concepts are relevant in so many different areas of application, from language instruction to professional writing (journalistic, official, legal, and political language) and from automatic text analysis to artificial intelligence. In fact, this pair of terms covers a wide range of far-reaching phenomena and properties that are found at the very center of the functioning of the linguistic system, such as referentiality, predication, the utterance-act, and information structure. The fact

that definitions (and applications) were developed in different scientific spheres means that they have focused to a varying degree on these different aspects, which has at times prevented a clear view of all the problems and all the results. In addition, the general phenomena referred to above belong not only to a primarily philosophical but also to an empirical dimension, and we are still uncertain how we can reconcile these different dimensions; it is difficult to give definitive answers using individual models.

Although there are points of convergence and a level of continuity among the definitions, differences remain because their origins lie in different traditions, and the concepts have been adapted by changing scientific and cultural contexts. Attempting to superimpose terms belonging to different fields and periods is therefore problematic. The definition of Topic as 'what is being talked about' and Comment as 'what is being said about what is being talked about,' which is characteristic of American Structuralism (see Sapir, 1921; Hockett, 1958), is based on the axiom that these two parts are present in every declarative

utterance. This is expressed in regulative terms by Lambrecht (1987: 254): “Do not introduce a referent and talk about it at the same time.” He affirmed that the relation Topic-of “expresses the pragmatic relation of aboutness that holds between a referent and a proposition with respect to a particular discourse” (Lambrecht, 1994: 127). For an element to be able to assume the Topic function, it has to be referential. Moreover, the relation ‘Topic of’ is defined in entirely semantic terms: “A referent is interpreted as a topic of a proposition if in a given discourse the proposition is construed as being about this referent, i.e. as expressing information which is relevant to and which increases the addressee’s knowledge of the referent” (Lambrecht, 1994: 127 and 131).

This type of definition and the axiom referred to above have their origins in a philosophical tradition that includes the whole history of Western thought. Although terms found in classical thought require accurate philological investigation and are not easily paired up with modern terms, one can argue that the splitting of an expression (*logos*) into “two inseparable semantic and referential functions” – *onoma* and *rhema* – was established by Plato and then taken up again by Aristotle (see Lyons, 1968; Lallot, 1988; Spina, 2002). Furthermore, linking referentiality to the utterance-act has an ancient provenance. The *onoma* signals actors and experiencers, whereas the *rheme* signals actions and events. Sometimes, the *onoma* is represented as content, and the *rheme* is represented as typically having an enunciative function (Spina, 2002; for an overview of the whole tradition, see Sandmann, 1979).

An underlying opposition has also been suggested for the notions of Theme and Rheme, as is found in European functional linguistics and text linguistics (see Halliday, Michael Alexander Kirkwood). In these fields, the pair is defined according to functional principles that are based on the speaker’s needs and communicative aims. Mathesius (1983:102) maintained, “Every bipartite utterance is composed of two components, the first of which expresses something relatively new and contains what is asserted by the sentence . . . The second part of the sentence contains the basis of the utterance or theme, the psychological subject according to earlier terminology, i.e. things relatively familiar or most readily available to the speaker as the starting point.” The order assigned here to the first and second parts invokes a hierarchy of importance, not some linear property of the syntagmatic structure. However, the linearization of Theme and Rheme is an area that has been investigated widely by Mathesius and other Prague School theorists (see Mathesius, 1924, 1939, 1941–1942; Daneš, 1985; Sgall *et al.*, 1986; Firbas, 1992).

The categories described by the Prague School are classical tools in discourse analysis that have precedents in philosophical thought concerning textual hermeneutics (see Schleiermacher, 1988). In actual fact, no textual analysis is possible without assuming a hierarchy of informative importance for parts of the texts with respect to the speaker or to the interlocutor. However, the Prague School and North American definitions are not as rigidly separated as one might think. Mathesius (1939: 174), for example, assimilated “that which is known in a given situation” to the “utterance’s starting point . . . from where the speaker begins,” defining the utterance’s nucleus as “that which the speaker asserts with respect to the starting point . . . or taking it into consideration.”

However, no matter how many early versions of these concepts and terms can be found, in modern linguistics, the Topic-Comment and Theme-Rheme pairs must be understood within the scientific traditions in which they were developed and in which they continue to be used (with some subsequent modifications). Even allowing for the differences between the North American and European scientific environment, both use linguistic concepts that have been influenced by schools of pragmatism. These trends have left their mark in various ways on functional approaches of the 20th century and, in certain respects, also on some fields of North American structuralism. In fact, the definition of both of these pairs assumes that the functioning of the utterance-act or of the discourse/text is a key criterion. All 20th-century models are based on the notion of functioning (the First and Second Prague Schools, Halliday, and Chafe), but the biases of each favor either the pragmatic or the semantic dimension. In the Prague tradition, the Theme and the Rheme are considered to be the units of the actual articulation of the sentence (Functional Sentence Perspective). This concerns “the way in which the sentence is inserted into the real context from which it comes” (Mathesius, 1939: 174). Indeed, “it is only the moment of actuality that creates a sentence from the words” (Mathesius, 1924: 171).

Topic and Comment, Subject and Predicate

Lack of Alignment between Pragmatic Functions and Semantic and Grammatical Functions

In many approaches, a correspondence (if not an exact correlation) is assumed between Topic-Comment and Subject-Predicate (see Sapir, 1921; Strawson, 1974; Lambrecht, 1994). In developing a “Relevance Principle,” Strawson (1974: 97) observed,

“Statements or the pieces of discourse to which they belong have subjects, not only in the relatively precise sense of logic and grammar, but in a vaguer sense with which [one] shall associate the words ‘topic’ and ‘about.’” Moreover, he noted that “stating is not a gratuitous and random human activity. We do not, except in social desperation, direct isolated and unconnected pieces of information at each other, but on the contrary intend in general to give or add information about what is a matter of standing current interest or concern” (Strawson, 1974: 97; cf. also Lambrecht, 1994).

Yet, the association of Topic-Comment and Subject-Predicate is problematic, because alongside the obvious similarities, there are also considerable differences. The first similarity lies in the actual nature of the relationship between the two parts. The question of whether the Subject is dependent on the Verb (Predicate) or whether the Predicate is dependent on the Subject has been discussed at length, and valid reasons have been proposed to support both theories (see Matthews, 1981; Graffi, 2001). However, it seems plausible to think that in each case both of the parts are necessary for the larger construction that they form (enunciation for T-C and phrase for S-P) and that they correspond and are mutually dependent (for more information on this model of interdependence or ‘solidarity,’ see Martinet, 1965 and 1985). There can be no Predicate without a Subject, and there can be no Subject without a Predicate; Predicate and Object, in contrast, are not linked by this kind of reciprocal relation. A second aspect that the two pairs of functions have in common concerns the canonical (or prototypical) semantico-pragmatic properties of each of the two parts: one carries reference, and the other carries the utterance-act/predication (for a philosophical account, cf. Strawson, 1974).

The differences are no less significant. Topic-Comment (T-C) or Theme-Rheme (T-R) is a representation that is anchored not at the syntactic level, but rather at a more general dimension defined as rhetorical-pragmatic (see below). In fact, it seems necessary to bring back into focus the traditional distinction among ‘utterance,’ ‘proposition,’ and ‘sentence’ as constructions that belong to three different dimensions; namely, the pragmatic, semantic, and syntactic. The T-C (or T-R) pair is concerned with the level of the utterance-act, and it constitutes its basic articulation. Its terms therefore need to be kept distinct from both Predicate-Arguments and Subject-Predicate, whatever similarities might exist between them. The utterance-act is defined by the speaker’s communicative intention or, in other terms, by his or her desire to mean something. This type of component is not

included in either the syntactic configuration or in the propositional scheme. A simple utterance such as:

- (1) John loves the sea

is not represented fully by either the phrase structure of traditional constituent analysis (or any more recent version of generative grammar):

- (2) [S[NP *John*] [VP[V *loves*] [NP[Det *the*] [NP
sea]]]]

nor by the propositional scheme:

- (3) $p(a, b)$, where p = ‘to love’, a = ‘John’, b = ‘sea’

but by a more complex structure that can be informally expressed as follows:

- (4) as for John, I am telling you that John loves the sea

The representation in (4) demonstrates that the syntactic configuration and the propositional scheme can only be considered subparts of the whole utterance. In particular, the p component of (3) forms a lower-level predicate, the semantic representation of which is defined by three properties: bivalency, the inherent lexico-semantic features of ‘to love’, and the capacity to combine with arguments that have specific semantic features. In contrast, the fact that an utterance like (1) has a pragmatic representation in which a declarative statement appears does not concern the propositional predicate: It is not something that is included in the properties of the predicate ‘to love,’ and neither is it part of its relations with the arguments ‘John’ and ‘sea.’ The declarative statement ‘I am telling’ must be represented as a predicate of a higher level. The differences between the representations of the syntactic structure (2), the proposition (3), and the utterance-act (4) can be expressed in relation to the well-known distinction between ‘mood’ (*modus*) and the statement’s content structure (*dictum*; see Bally, 1944; Graffi, 2001). The constituent that has predicative function in a sentence configuration and the predicate of the logical-semantic scheme are part of the statement’s content structure. The higher predicate ‘I am telling’ is the mood of the utterance-act. It is not necessarily realized by phrase structure or by any other kind of segmental shape; in many languages in fact, it is normally realized by intonation. Yet, in order for an utterance-act to be formed, it must be present in any case.

Based on this schema, one can say that the division of Topic and Comment constitutes the basic structure of representations like (4). The relationship between T and C is defined by a predication at a higher level than that belonging to the predicate ‘to love.’ This kind of predication can be represented by the

illocutionary force of statement. The Topic function does not coincide with the Subject any more than the Comment does with the Predicate. Topic and Comment belong to an organizational level that is logically higher, and their relation is determined by the declarative mood.

Significant proof of this theory is found in a well-known empirical feature that distinguishes subordinate clauses from main clauses. Only the latter can have a Topic-Comment articulation, whereas the former do not. In fact, the illocutionary force of statement is a fundamental part of the representation of main declarative clauses, whereas subordinate clauses have only the statement's content structure in their representations. The fact that, in some approaches, like the Second Prague School (see Svoboda, 1968; Firbas, 1992), subordinate clauses have been divided into Theme and Rheme illustrates a further aspect of the conceptual difference between the two pairs of terms.

Representations like (4) can account not only for utterances like (1), where the statement's content structure is made up of a Subject – (transitive) Predicate structure but also utterances where the statement's content structure has Subject – (intransitive) Predicate structure, as in (5) with the corresponding representation of the utterance-act (6):

(5) John is coming

(6) as for John, I am telling you that John is coming

Yet, not all utterances with single-arguments in the statement's content structure have a representation like (6). So-called presentative orthetic utterances like (7):

(7) JOHN is coming

that are marked in English by a focal accent on John and in other languages by the order VS do not easily conform to the Topic-Comment split. According to a line of thought that has gained wide consensus, utterances like (7) lack the Topic-Comment articulation and the Theme-Rheme split. They can be analyzed according to two different interpretations, depending on the context. In one, *John* is in Focus (in this case, the utterance has the pragmatic presupposition that someone will come), and in the other, the whole statement's content structure is in Focus (in this case, the pragmatic presupposition can be expressed by the question "what's happening?"). In the latter interpretation, single-component structures like (7) are opposed to bipartite T-C or T-R structures. This tradition of linguistic thought was influenced by the distinction made by Kant between *a priori* 'analytic' judgments and *a posteriori* 'synthetic'

judgments, which are typically bipartite, and existential judgements that have no predicate. Marty reinterpreted the Kantian distinction by opposing "categorical" judgments that are bipartite and "thetic" judgments that are simple, having only one member (see Ulrich, 1985).

In this respect, there is an interesting difference between some Topic-Comment models that are in wide use today and the Theme-Rheme models from the Prague School. According to the first type, Topic is absent because this type of function needs to be realized by a constituent that has a high position in the referentiality hierarchy; canonically, this would be a NP. According to the second type, in contrast, the bipartite articulation is legitimate if (7) is interpreted as having only *John* in Focus: The verb 'to come' would be the Theme, and *John* would be the Rheme.

However, these analyses are problematic. The two interpretations of (7) could correspond to the representations of the utterance-act (8) and (9):

(8) I'm saying that the person who is coming is John

(9) I'm saying that what is happening is that John is coming

Yet, such representations can be considered, respectively, equivalent to the following:

(10) As for who is coming, I'm saying that the person who is coming is John

(11) As for what is happening, I'm saying that what is happening is that John is coming

The fact that the Topics of utterances like (7) are not realized in the linguistic structure does not prevent the analysis of the utterance-act from containing representations that make them explicit; the utterance-act also includes elements that are not verbally expressed but present in the context. This has at least two implications: (1) the distinction between elements that carry reference and elements that carry the predication, at the pragmatic level, might be more complicated than is often thought, and (2) the T-C and T-R models can be transcoded.

It becomes particularly obvious that we need representations of the utterance that are not limited to the canonical forms of configurational and propositional representation when we look at utterances whose syntactic structure contains constituents that do not have traditional Grammatical Functions. Utterances with various types of left dislocation and hanging topics, like (12), (13), and (14)

(12) John, I saw him yesterday

(13) John, I lent him the book

(14) John, his house is a complete mess

do not have identical functions: The Subject and Object (either direct or indirect) functions evidently belong to a level of representation different from that at which the Topic function is found. This question has recently been tackled in the so-called discourse configurational models of generative grammar (cf. Kiss, 1995). These models define two discourse semantic functions, Topic and Focus, the first “serving to foreground a specific individual that something will be predicated about” and the second “expressing identification” (Kiss, 1995: 6). Although this may seem a major departure from traditional generative models, which define the Topic function in purely configurational terms, the main orientation still remains on the study of how the two discourse functions are expressed through a structural (i.e., configurational) relation. In other terms, the discourse configurational models only account for the structural projections of a Function that itself belongs to another level of representation.

What has been said so far allows further consideration of the parallels between the Subject-Predicate and the Topic-Comment functions. The former defines the sentence and the latter the utterance. Both relations are crucial for functioning, at different levels. Through them, what were simple groups of elements become meaningful units at the sentence-level and carry indexical values at the utterance-level. It is at the latter level that they properly become communicative units.

Structural Implications of the Differences among Pragmatic, Semantic, and Grammatical Functions

The pragmatic and semantic differences discussed here have significant consequences for the structural level. They also involve different formal properties. In languages in which the Subject function is morphologically encoded (this is realized by the relevant Noun Phrases and/or by the heads of Verb phrases of which they are made), such encoding does not necessarily match the structural projection of the Topic function. For example, if the linguistic system has Case marking on the Subject, this might not be required for the Topic, or it could be realized by Case marking that is not the same as the Subject's marking. Similarly, if a language has agreement between Subject and Verb, the same might not apply to the constituents that realize the Topic and Comment functions. In general, the range of types of constituents that can have the Topic function (or the Comment function) is larger than the range of types of constituents that can have the Subject or Predicate functions.

Another group of structural properties that distinguish Subjects from Topics concerns the movement properties of the relative constituents within the sentence. In certain models, the Topic function is determined by linearity. It is associated with the first or one of the first positions of the proper domain of the sentence or with an extra-sentential position to the left of the proper domain (see Graffi, 1994; Dik, 1997). The movement of the Topic constituent to another position in the sentence, in particular toward final or extra-sentential positions to the right of the proper domain (the Tail), generally leads to the constituent losing the Topic (or Theme) function. Nevertheless, the fact that there is a significant statistical correspondence across the world's languages between the basic Subject position and the Topic function appearing in the initial position (see Comrie, 1981; Tomlin, 1986) cannot be taken as conclusive proof that Subjects and Topics should be considered to be structurally equivalent. In fact, in many languages the range of grammatical functions whose constituents can occupy the initial positions of the proper domain of the sentence is not limited to the Subject function alone. One need only think of relatively common processes, such as left dislocation of direct or indirect Objects.

Finally, there are also substantial differences in the referential endophoric properties. In many languages, the grammatical Subject constituents have control properties over anaphors that the Topic constituents do not have. All the structural differences mentioned so far have implications for both typology (cf. the Topic-prominent vs. Subject-prominent language dichotomy presented by Li and Thompson, 1976 and widely used in typology) and Universal Grammar (see the important study of Keenan, 1976).

To sum up, the set of the structural properties defined by T-C, T-R and the set of structural properties defined by Subject-Predicate intersect, but do not wholly overlap. In particular, the set of constructions that realize T-C functions is larger than the set of constructions that realize the syntactic functions Subject-Predicate.

Similarities and Differences among Various Models

The concept of Topic as an element that limits or restricts the field of the predication (Chafe, 1987) is based on structural properties (for example, the fact that the Topic needs to precede the predicate) and lexico-semantic properties (specifically, contiguity and isotopy). The definition of Theme as the ‘Base’ or starting point of the utterance (Mathesius), or the part that conveys the lowest level of Communicative Dynamism (Firbas, Svoboda), depends on linear

principles of functioning that are to some extent independent from the grammatical organization. To a certain extent, one can say the same for the GIVEN-NEW and for the KNOWN-UNKNOWN parameters, all of which are used widely in text linguistics. These parameters are based on the lexico-semantic and compositional properties of units in relation to larger sections of text; however, they also constitute pragmatic categories related to the functioning of the utterance-act. Similar observations can be applied to the notion of 'Focus' in Tagmemics (see Pike, 1982) and the recent versions of the Focus function (see Rebuschi and Tuller, 1999 and, which show similarities to the notions of Comment and Rheme. This is also the case for the definitions of Topic either as the center of attention (see Chafe, 1976) or as a most accessible element (see Givón, 1985; Chafe, 1994) that are based on cognitive properties.

In many models, two different pragmatic and semantic approaches are merged: one according to which the meaning and information of units depend on their referential indexes, determined by the context, and the other according to which the meaning and information of an utterance depend on the 'functioning,' or to be more precise, on the actual dynamics with which the speakers plan and perform the discourse in relation to the listeners. It is generally the case that in all the models the relationship between meaning and information remains an open question (but see the interesting proposals presented by Bar-Hillel and Carnap, 1964; Harris, 1991). However, the centrality assigned to indexical coordinates to a greater or lesser extent (see Bar-Hillel, 1954, 1970) is a criterion that appears to have been employed in a more general way than the concept of 'functioning,' albeit at different levels of theoretical development. This kind of characteristic in fact can be used as a distinctive criterion to determine the degree of pragmatic orientation of a model. Another criterion for pragmatic orientation concerns the speaker-listener dimension: Base, GIVEN, NEW, Focus, accessible element, and center of attention are all categories related to the speaker and the listener.

However, a question emerges that has so far remained unanswered: whether the categories defined according to the speaker are the same as those defined according to the listener. The fact is that the two types of categories do not necessarily coincide: what is Topic for the speaker might not be for the listener and vice versa. In fact, an important difference among the functional models concerns the bias toward production or comprehension of the utterance/text. If concepts like GIVEN and NEW or the hierarchy of communicative dynamism seem to be ambivalent, 'Base' perhaps displays a bias toward production

and 'the most accessible element' is biased toward comprehension. The bias often remains implicit, but has important consequences for the modeling itself.

Topic-Comment Articulation and Spoken Discourse

Two questions often discussed concern the hypotheses that the Topic-Comment articulation is characteristic of spoken discourse and that it has a more basic character than the Subject-Predicate articulation. Indeed, several psycholinguistic studies seem to show that in the process of language acquisition the structures that have the grammatical properties of Subject-Predicate appear after the structures that are grammatically heterogeneous and that are reducible to the general Topic-Comment articulation (cf. MacWhinney and Bates, 1978 and, for second language acquisition, Klein and Perdue, 1992). There is no question that analyses of oral corpora of languages that have grammatically articulated Subject and Predicate show numerous structures that do not conform to patterns in which the Topic is a Subject NP and the Comment is a canonical VP. Yet, the two hypotheses proposed are difficult to test empirically. One reason is that phenomena with very diverse structural characteristics are often grouped together under the label of T-C, which means that results obtained across a variety of research areas are incompatible.

Statistical calculations have been done on a range of languages through corpora in an attempt to determine the occurrence rate of structures that are traditionally considered to be examples of the T-C split, such as hanging topics, left dislocations, etc. However, it is questionable whether the results obtained in this way can definitively prove the prevalence of such structures in spoken discourse because of the great variety of linguistic and extra-linguistic conditions that can apply to both spoken texts and written texts. To sum up, without excluding the fact that certain structures like (13) and (14) are in reality characteristic of unplanned spoken discourse, in general the hypotheses discussed may have methodological rather than theoretical value. In the analysis of spoken discourse, categories, such as Topic-Comment or Theme-Rheme, may prove to be more useful than purely syntactic categories.

Cognitive, Interactional, and Textual Dimensions

The representation of Topic and Comment in cognitive terms, common in some North American functional schools, has important precedents in the history

of linguistic thought. During the second half of the 19th century, a lively debate emerged about the notion of Subject and Predicate, in which the grammatical categories were defined psychologically by some scholars (see Graffi, 2001). Paul (1920: 87) defined the Psychological Subject as “the first retrievable complex of psychological representations in the consciousness of the speaking and thinking being” and the Psychological Predicate as “the second [complex of psychological representations] that is connected to the first.” Although he acknowledged that the grammatical Subject and Predicate do not always correspond to the psychological Subject and Predicate, Paul nevertheless believed that “the grammatical relations are based on the psychological relations” (1920: 111). Interest in the psychological dimension has always been present in linguistics, in particular in certain functional schools. However, in the Prague School, psychology was considered to be a discipline entirely auxiliary to linguistics (Mathesius, 1924).

In North American functional studies, topics have been defined at sentence-level (the micro-level) as constituents that have referential features or rather as ‘participants’ in the semantic scheme (see Foley and Van Valin, 1984; Givón, 1985; Chafe, 1994; Lambrecht, 1994). This definition has often been used in linguistic typology, particularly after Comrie (1981; see Prepper, 2001). Discourse topics have been defined as “aggregate[s] of coherently related events, states, and referents that are held together in some form in the speaker’s semi-active consciousness” (Chafe, 1994: 121). Givón (1985) believed that the definition of Topic as an atomistic, singular, and discrete unit at the sentence-level (the so-called micro-topic) should be replaced by a model that represents a plurality of sentence topics and the permanence or continuity of these text participants. In each case, these studies were based on a semantic assumption about the representation of ideas; namely, that events and states and the referents that participate in them make up the basic cognitive network of the speakers and the listeners (see Givón, 1985; Chafe, 1994). This model has an equivalent in the so-called ontologies in use today in artificial intelligence. The analyses of Topic continuity can in fact have numerous applications in this sector and also in computational linguistics.

Topic and Comment: Between Reference and Relationship

The property traditionally ascribed to the Topic function – namely, its capacity to contain elements that carry reference – is neither a necessary nor a sufficient condition for topicality. The fact that Topic

has recently been reinterpreted in relation to a referential hierarchy of access to the function (Topics tend to be elements high up on the hierarchy of referentiality) shows that it is not a necessary condition. For example, there are adjectives or verb forms with no finite marking that can perform the Topic function in many languages. Moreover, not all referential elements are Topics. Referentiality simply defines a relation between an element and an exophoric context (that is to say, extra-linguistic) or an endophoric context (that is to say, intratextual). In contrast, topicality is a purely textual function, linked to the flow of information in the text: For an element to be a Topic, it must be part of an informative progression where something is being said about it or, more precisely, more information is being added about it. In other words, for an element to be a Topic, it must be true that other information will be added about it. As has been said, the models of textual Topic-continuity rely on referential characteristics, whereas sentence-oriented models are based on the relational characteristics of Topic and Comment. In the latter, the similarity with the syntactic functions of Subject and Predicate – also inherently relational – is therefore emphasized.

Translation, Pragmatics

Introduction

Pragmatics has become increasingly important in the study of translation. This is the result of a number of shifts in the way translation itself has been approached. This includes, first, the fact that we have begun to look at translation more and more as just another type of language use, indistinct from other ordinary language uses (apart from the fact that it involves two languages). Second, this shift has made it possible to consider translation as falling under the remit of verbal communication, thereby allowing us to study it within pragmatics. Finally, new developments in pragmatics have enabled us to unify the study of all types of language use, including translation, under a single pragmatic theory, thus allowing us both to simplify the study of translation and to bring it closer within the sphere of verbal communication. The end result of these shifts has been that translation now is seen as just one more instance of verbal communication and consequently, as being subject to the same principles of verbal communication that govern all utterance interpretation (both intra- and interlinguistically). (see **Intercultural Pragmatics and Communication**.)

The shifts in the overall approach to translation have only taken place very gradually over the last 20 years or so and in the context of an unsystematic and fragmented study of translation. This entry reviews these changes and discusses how pragmatics has come to solve earlier problems and to play an increasingly central role in the discipline. (see **Pragmatics: Overview**.)

The article is organized as follows. First, the gradual shift toward pragmatics within translation is discussed briefly. Then, some of the current key pragmatic concepts, as applied to translation, are introduced. Finally, the results are discussed, and some conclusions are drawn.

A Brief Overview of Approaches to Translation

The study of translation has traditionally been approached from two different points of view: one is non-theoretical, the other more theoretically oriented (for an introduction to translation studies, see, e.g., Munday, 2001).

The non-theoretical approaches to translation maintain that translation is not primarily an act of communication, but rather an art, an intuitive endeavor, and that as such is not amenable to scientific treatment. This is the stance taken by a scholar such as Steiner, who argues that in translation “what we are dealing with is not a science, but an art” (1975: 295). Similarly, Newmark (1988: 19) argues, “[i]n fact translation theory is neither a theory nor a science, but the body of knowledge that we have and have still to have about the process of translating.” These non-theoretical approaches have been very influential in the study of translation, in that many scholars have seen their role as restricted to the production of lists of recommendations that could guide translators in their work. However, it has been generally acknowledged that one of the main problems with this type of approach is its inherent limitation as regards scientific enquiry and as to the type and degree of explanation achievable. In other words, from this point of view, at most we are likely to achieve a set of observations about translation; there will not be any systematic development of an underlying theory that would allow us fully to explain the phenomena involved in translation. Inevitably, as communication plays no central role in these non-theoretical approaches, the contribution of pragmatics is limited.

The more theoretically oriented approaches to translation have attempted to solve the inherent limitations of non-theoretical accounts. Broadly speaking, two types of approach can be identified: the first type is multidisciplinary and the second equivalence-based. The multidisciplinary approaches have tried to consider the various influences that can be observed in translation, with a view toward shedding some light on the processes involved. They have attempted to do this by exploring the impact on translation of diverse disciplines such as linguistics, literature, cultural studies, anthropology, etc. Multidisciplinary approaches have been influential in opening up the study of translation to many disciplines and in enabling researchers to explore a wide range of influences on the process of translation. However, one of the main problems with this type of approach has been the lack of a coherent and systematic account, giving rise instead to a highly fragmented study of the discipline and to inevitable limitations in the development of a unified theory of translation. Within this type of approach, the role of pragmatics has, at best, been one among many contributions to the field; pragmatics has not played any systematic or central part in its development.

The first major approach that allowed us to develop a more systematic and coherent account of translation was one based on the notion of equivalence (for an introduction, see Baker, 1992). This approach is part of an array of theories that are ultimately based on a structuralist view of translation and on the code model approach to communication (for an introduction to some of these theories, see Munday, 2003). The equivalence-based approach involves an important theoretical shift in that it is one of the first major attempts not only to develop a systematic and explanatory account of translation, but also to include explicitly the role of pragmatics in translation (in particular, Gricean pragmatics). (see **Grice, Herbert Paul; Pragmatics: Overview.**) Equivalence, in the context of translating, implies that the aim of a translation is to produce a target language text which is equivalent to the original language text. This represents an improvement on earlier approaches in that here there is a purpose and a guiding principle in the production of translations, as well as an explanation for the choices made by a translator, both in the process of translation and in the production of target texts.

The equivalence approach to translation has also been influential in that it has enabled practitioners to apply more consistent criteria to the study, practice, and evaluation of translations. From a pragmatic point of view, it has made it possible to include equivalence features at the pragmatic level (such as reference, coherence, implicatures, pragmatic maxims, etc.). (see **Maxims and Flouting; Implicature.**)

Even so, the equivalence approach, systematic as it may seem, lacks definitional precision. Baker herself, whose entire 1992 book is based on the notion of equivalence, acknowledges the shortcomings of this concept: “equivalence is adopted [...] for the sake of convenience – because most translators are used to it rather than because it has any theoretical status.” (Baker, 1992: 5–6). The approach has also been shown to face other serious problems (see Gutt, 2000: Chap. 1), particularly as a result of the insights gained in current studies in pragmatics and human communication. What these problems have in common is the insight that equivalence is at best a descriptive concept, not an explanatory one, and that it ultimately relies on other concepts that are external to its definition (i.e., equivalence is not a sufficient criterion in and by itself). So how can these problems be addressed?

Translation, Communication, and Pragmatics

A suggested solution to the problems mentioned above places the study and practice of translation

more firmly within verbal communication and pragmatics (thus making it more amenable to scientific study). As Hatim and Mason (1997: vii) state, “we look at all kinds of translating as essentially *acts of communication* in the same sense as that which applies to other kinds of verbal interaction” (my italics). Gutt (2000: 23) argues along the same lines: “Translation is indeed best handled as a matter of communication.” He similarly argues that “issues of translation are at heart issues of communication” (Gutt, 2000: 198). This line of enquiry, which sees translation as an instance of verbal communication, is the main link between pragmatics and translation in current research on the subject.

The chief proponent of a consistent and systematic application of pragmatics to translation has been Gutt (2000), who has applied one of the main current pragmatic theories, viz., Relevance Theory, to the subject (for an introduction to Relevance Theory, see Blakemore, 1992; Sperber and Wilson, 1995). (see **Relevance Theory.**) Relevance Theory allows us to approach the study of translation as an act of communication, in a systematic and explanatory fashion. A number of key assumptions make this possible. As Blakemore (1992: 39) argues, “[t]he search for relevance is something that constrains all communication, verbal and non-verbal.” (Gutt, 2000: 198) goes further and maintains that “the principles, rules and guidelines of translation are applications of the principle of relevance.” He further claims that “given the general framework of relevance theory, no special, additional concepts or theoretical tools are needed to accommodate translation” (Gutt, 2000: 237). The latter claim has profound and far-reaching implications for translation, as it amounts to saying that there is no need for a theory of translation as such. Instead, translation is seen as just one more instance of verbal communication, with the particularity that it involves two languages. Thus, from this point of view, translation can be studied fully within pragmatics (which thereby becomes its proper theoretical domain).

There are a number of advantages of this approach over earlier ones. First, there is no need to construct extra theoretical machinery to account for translation. Second, all the separate and diverging claims that have been made about translation can be seen as natural applications of the principle of relevance and, therefore, can be unified under a single explanatory theory (rather than being isolated claims without internal theoretical foundation or coherence). (see **Communicative Principle and Communication.**) Third, translation can benefit directly from advances made in our understanding of verbal communication, pragmatics, and cognition (which contrasts with the earlier situation, when translation was

treated as an isolated discipline and had to borrow concepts from widely diverging areas of research, something that resulted in the absence of a unified account). Finally, in contrast with, e.g., equivalence approaches, an approach based on Relevance Theory provides explicit definitions for its theoretical framework, which is intended to be universal in its application and univocal in its search for intended interpretations of texts/discourses.

For a translation theory based on the notion of relevance, the challenge has been to spell out the implications for translation of all of the above claims as well as of the specific theoretical claims made within Relevance Theory proper. So far, two areas of research have been developed in this respect: one at the macro level and the other at the micro level. By far the biggest contribution in this endeavor has been achieved at the macro level (see, in particular, Gutt, 2000); here the driving interest has been the theoretical characterization of translation as an instance of verbal communication to be studied within pragmatic theory. In this respect, Gutt (2000) argues that the key notion in any account of translation is that of resemblance, both interpretive and non-interpretive. He claims that for a target text or discourse to be a translation, it has to enter into a relationship of resemblance with the original text/discourse (in which resemblance is defined as the extent to which two representations share properties such as semantic content, linguistic features, sounds, etc.). In particular, the main focus of research has been interpretive resemblance, which focuses on the resemblance of content between original and target texts (i.e., the extent to which they share analytic and synthetic implications). For a translation to be successfully communicated, so it is claimed, it must (interpretively) resemble the original in an optimally relevant way. More recently, researchers such as Almazán García (2001) have argued that the notion of interpretive resemblance must be substituted by that of meta-representation in order to cover all possible cases of translation. However, as matters stand, there does not seem to be enough evidence to suggest that the notion of resemblance should be unable to by itself account for all translation cases (cf. Gutt, 2000: 198).

There are a number of advantages in characterizing translation as interlinguistic resemblance within the approach provided by Relevance Theory. For example, such a characterization allows us to understand why some translations are more direct than others (e.g., when issues of close resemblance are relevant, as in literary translation); or why it is sometimes necessary to include background information in the target text (e.g., when contextual assumptions would not otherwise be available to trigger the intended

contextual effects, as in translation across very different cultures). Thus, research at this macro level has been fundamental to the application of pragmatic theory to translation; it also has made its application possible at the micro-level.

At this level, the prevailing interest has been to explore in more detail the processes and products that result from seeing translation as an act of communication (see, e.g., Rosales Sequeiros, 2002). Here, a key assumption is that the translator is not only a receptor of the original text but also a communicator of the target text. This presents us with a double role for the translator in communication, which (together with the gaps that necessarily exist between what is encoded and what is communicated in linguistic communication) gives rise to an array of textual and communicative effects in translation (e.g., discrepancies between original and target texts). These effects can be seen at all pragmatic levels, including the word/concept level, the referential level, the propositional level, and the level of implicature, among others. In all these cases, we find that translations often differ from the original texts as a result of the communicative processes experienced by the translator during the interpretation of the original text and the rendering of his/her interpretation in the target text. In these cases, we find that pragmatic theory allows us to explain the discrepancies found between the two texts and, in turn, helps us in our evaluation and acceptability judgments of target texts. This insight also allows us to understand and unify, within a single theory, a wide range of translation discrepancies. For example, it allows us to determine when direct translations are not possible (e.g., when the linguistic structures of the two languages are not capable of the same degree of explicitness); or why certain discrepancies recur in translation (e.g., when the translator renders into the target language not what is encoded in the original text but, rather, what is communicated). In general, research at the micro level allows us to understand and predict the potential problems faced by translators in the process of translation, and thus alert practitioners to possible solutions.

Conclusion

Seeing translation as an instance of language use, and consequently studying it within the framework of verbal communication and pragmatics, has resulted in pragmatics playing an increasingly important and central role in the study of translation. This shift, as well as other current developments within pragmatic theory, has enabled us to unify the study of translation within a single theoretical approach, viz., that of Relevance Theory.

Relevance Theory allows us to simplify the study of translation both by doing away with the need for a separate theory of translation and by allowing us, instead, to indistinctly apply the same concepts used in other types of language use to translation. Translation is specific only inasmuch as it involves two languages and inasmuch as the target text is purported to resemble the original text. These contextual assumptions play the same role in the interpretation process as does any other contextual assumption. All the other observable and cognitive processes involved in translation can be explained and accounted for by pragmatic principles and processes covered within Relevance Theory.

Within the relevance-theoretic approach, research on translation has focused on two main areas. On the one hand, there has been an interest at the macro-level in characterizing translation as a communicative event involving interlinguistic resemblance between two texts or discourses. On the other hand, there has been an interest at the micro level in understanding the cognitive and communicative processes experienced by translators as receptors and communicators, and the effects these processes have on the products of translation.

Future pragmatic research on translation is likely to continue to focus on the two levels indicated above, as it attempts both to specify the communicative nature of translation more precisely and to understand the changes in target texts and discourses caused by the communicative process of translation.

Traugott, Elizabeth

S-H Seong, University of Bonn, Bonn, Germany

© 2006 Elsevier Ltd. All rights reserved.

Elisabeth Closs Traugott is a Professor Emeritus of Linguistics and English at Stanford University in California. She began her undergraduate studies at Oxford University in 1957 and completed her graduate studies at the English department of the University of California at Berkeley in 1964. She held an assistant professorship in the Department of English at Berkeley from 1964 to 1970. In 1970 she became an Associate Professor of Linguistics and English at Stanford and has held full professorship at the same school since 1977. Traugott has also been a Fellow at the Center for Advanced Study in the Behavioral Sciences, and a Guggenheim Fellow.

Traugott has conducted research on historical syntax and semantics, sociohistorical linguistics, and linguistics and literature. Her first major publication is *A history of English syntax: a transformational approach to the history of English sentence structure* (1972). This book analyzes the fundamental constructions and events of English historical syntax (changes in the verbal system, in surface case forms, in dominant word order types, in negative and interrogative sentence patterns, in complementation and relativization, among others). Traugott also examines several instances of foreign (French, Latin, Old Norse) influence on English syntax. This work excellently summarizes the research tradition in the field of historical syntax. The chapters include Modern English syntax, Old English, Middle and Early Modern English, and Modern English since 1700. While this research manifests a Chomskyan influence, it is also supplemented by performative analysis and case grammar.

Her other research contributions focus on language change, particularly grammaticalization, lexicalization of conversational inferences, and subjectification; clause combining, particularly conditionals, concessives, and causal clauses. Some of her important articles in these areas include 'And and But

connectives in English' (*Studies in language*, 1986), 'On the rise of epistemic meanings in English: an example of subjectification in semantic change' (*Language*, 1989). With respect to clause combining, the investigation of the historical paths of English connectives *and* and *but* shows that there is a strong tendency for spatial and temporal meanings to give rise to logical connective meanings. In regard to the subjectification process in semantic change, it is demonstrated that "meanings tend to become increasingly situated in the speaker's subjective belief state or attitude towards the proposition." The semantic changes of modal auxiliaries (e.g., *must*), assertive speech act verbs, and modal adverbs show that epistemics develop from more root, deontic, and concrete meanings to more strongly subject epistemicity.

Her seminal book *Grammaticalization* (1993; 2nd edn. 2003, with P. Hopper) deals with historical as well as synchronic linguistics whereby "lexical items and constructions come in certain linguistic contents to serve grammatical functions, and, once grammaticalized, continue to develop new grammatical functions" (2003: xv). This change corresponds to the shift of content words to pure function words.

Traugott also co-authored *Regularity in semantic change* with R. Dasher (2001) in which cross-linguistic unidirectional tendencies in semantic change are discussed in detail. Her writings also include *Linguistics for Students of literature* (1980; with M. L. Pratt), and *On conditionals* (1986; co-edited).

Understanding Spoken Discourse

Introduction: the Contextual Specificity of Spoken Interaction

To characterize spoken discourse requires us to specify the very different contexts of utterance which occur in the production and reception of spoken and written discourse. These configurations largely explain the rather different properties of spoken and written discourse, even allowing for equivalence of register and formality: see the well-documented account of crosslanguage spoken syntax and discourse in Miller and Weinert (1998).

Speech prototypically involves face-to-face interaction between two or more participants who share a spatiotemporal environment. This, together with a common cultural and personal background in the case of conversationalists who know each other well, provides a rich contextual common ground, allowing the speaker to avoid having to verbalize a number of aspects of his or her message. At the same time this common ground enables the discourse participants to rely to a large extent on nonverbal signaling, in tandem with and even, on occasion, in place of, the verbal textualization of a given utterance. Planning time, as well as ‘understanding’ time, is naturally minimal and at a premium – and a great many features of spontaneous speech flow from this key factor. Moreover, both speech and writing are normally designed by the user so as to be readily understood by the addressee (cf. the notion of ‘recipient design’). Indeed, according to Clark (1996) and other linguists, conversation and communication in general is a fundamentally joint activity, involving the active participation of the interlocutors and the coordination of their actions (verbal as well as nonverbal).

What I have just (very briefly) characterized is of course the prototypical instance of spoken interaction. There are obviously other less prototypical

types of spoken discourse: for example, speaking on the telephone, where the participants share a time frame (adjusting for time zone differences when the call is international) but not a spatial one, where only two participants are involved, and where the communication is ‘ear to ear’ rather than face to face (no nonvocal gestures or visual percepts are possible): see Drummond and Hopper (1991) for a discussion of miscommunication over the telephone; and speaking in a formal situation (a speech, lecture, and so forth) in front of a group of people in circumstances where convention does not normally allow for verbal exchange and interaction.

In written discourse, on the other hand, there is by definition no common spatiotemporal ground between the writer and his or her reader(s). Since this is the case, and since inevitably there will be little or no opportunity to use nonverbal signals, the text used will need to be relatively explicit – since the textual input is confined to the verbal content, in conjunction with punctuation and various graphic devices. The much greater availability, in principle, of planning time allows the writer to review and to amend his or her written production.

The Context of Spoken Discourse, the Distinction between *Text* and *Discourse*, and their Roles in Understanding

It is useful in analyzing spoken (as well as written) discourse understanding to draw a three-way distinction between the dimensions of *text*, *discourse*, and *context*. Definitions which I find helpful are given below (see Cornish, 1999: §2.3 and 2003: §2 for further development and illustration of the ‘text’/‘discourse’ distinction, and its importance for anaphora; also Edmondson, 1981: 4; Seidlhofer and Widdowson, 1999; and Werth, 1999: ch. 5 in connection with the notion ‘context,’ on ‘Common Ground’ within his ‘Text Worlds’ framework):

Text, discourse and context

Text: the connected sequence of verbal signs and nonverbal signals in terms of which discourse is

coconstructed by the participants in the act of communication.

Discourse: the hierarchically structured, situated sequence of indexical, propositional, utterance and illocutionary acts carried out in pursuance of some communicative goal, as integrated within a given context.

The *context* is subject to an ongoing process of construction and revision as the discourse unfolds. It is through the invocation of a relevant context (which is partly determined by the nature of the cotext at issue, as well as by its genre) that the hearer or reader is able to convert the connected sequence of textual cues that is *text* into *discourse*. (Extract [slightly amended with permission from Mouton de Gruyter] from Cornish, 2003: 3.)

The text is the perceptible record of at least one utterance act (whether realized in terms of a verbal, linguistic trace or of a nonverbal trace – which may be gestural, sensory-perceptual or prosodic). See especially Clark (1996), chapter 6, on nonverbal signals and their different kinds of function in discourse. Clark draws a highly relevant distinction between two simultaneously functioning textual ‘tracks’ which operate in spoken discourse: a primary track, where the ‘official business’ of the transaction at hand is conducted; and a secondary ‘metadiscursive’ or discourse management track, where participants make explicit the purposes and functions of the preceding and ongoing talk. The functions of either track may be realized via verbal and nonverbal signals (whether in tandem or individually). We shall be looking at examples of this dual-track structure in operation shortly.

The notion of *text* is close to what Gumperz (1992: 234) calls “contextualization cues.” The discourse partners make use of this record (a dual-track one, according to Clark, 1996), in conjunction with their invocation of a relevant *context* in cognitive terms, in order to create discourse.

Discourse, on the other hand, refers to the hierarchically structured, mentally represented product of the sequences of utterance, propositional, illocutionary, and indexical acts which the participants are carrying out as the communication takes place. Such sequences have as their *raison d’être* the accomplishment of some particular overall communicative goal (see Parisi and Castelfranchi, 1977).

The crucial point about this distinction is that discourse is a (re)constructive, and therefore highly probabilistic, enterprise: from the addressee’s perspective, it is by no means a question of simply directly **decoding** the text in order to arrive at the fully fledged message originally intended by the addressor. Indeed, the addressee actively contributes both to the text and to the discourse via his or her phatic signals,

indications of (mis)understanding, and other reactions to the speaker’s moves. Meaning does not lie ‘in’ the text; it has to be constructed by the addressee (and the speaker!) via the text and an appropriate context (cf. Coupland *et al.*, 1991: 5). In any case, the text is often, if not always, both incomplete and indeterminate in relation to the discourse which may be derived from it in conjunction with a context.

Some Aspects of Understanding Spoken Discourse

Inferring Propositional Content and Illocutionary Force

In what follows, I shall be examining instances of (mis)understanding which occur, and are manifest, **within** conversations. So it is the monitoring by the discourse participants themselves of the discourse being co-constructed that is at issue here. I am adopting the principle that it is when misunderstandings, disagreements, or disruptions generally are manifest in the textual record of a conversation that the way in which discourse normally operates may be seen most clearly (cf. Coupland *et al.*, 1991). Let us analyze an initial occurrence of such a phenomenon. Here is a segment from the BBC Radio 4 cultural discussion program *Start the Week*. The previous speaker (Caroline Quinn) has been arguing that the alienation of black people in the United States is not due to a single factor, but has a variety of causes; that the situation is improving for all racial groups in the United States, and that differences in degrees of integration into U.S. society are in part due to differences in the ‘cultural inheritance’ which each group brings with it. Homi Bhabha is then given the floor (for a second time) by the presenter, Melvyn Bragg. Notational symbols used here are as follows: – : pause; — : double pause; upper-case letters: strongly accented syllable; [...]: simultaneous speech; = : latching; (a): elision of ‘a’; .hhh = sharp intake of breath. See Cameron (2001), chapter 3 and Schiffrin (1994), Appendix 2 for details of spoken discourse transcription.

HB: Kate Kate – Caroline – you know I’m SURE you didn’t mean it but sometimes – cultural inheritance shades off into biological inheritance – in in the States you know people say .hhh – Blacks are in some – inherent way – inferior – an’ there’s a lot of – a lot of a lot of stuff going around now of course – American Blacks came as slaves it’s not what they brought with them it was what they were not – Able to bring with them they were [snatched – no but – —]

CQ: [it’s no – it’s nobody’s fault] =

Idem: = no I'm not saying it's anybody's fault – but I'm just saying you know that that's the brute – historical – FACT...

In track 1 here, Caroline Quinn asserts that the fact that black slaves were forced to sail to America without taking any of their possessions with them was not **their** fault (this is the proposition actually intended to be conveyed by the speaker here). It is no doubt the extreme sensitivity of the issue (racism towards Blacks) that has motivated the use of the indefinite negative with wide scope, *nobody*, here. (This is also the motivation for HB's intake of breath in line 4, just before his presentation of the [racist] view of Blacks in the United States.) And in track 2, the same speaker is rejecting what she sees as Homi Bhabha's illocutionary stance in the extract – justifying and even seeming to condone the fact that black people in the United States are still not considered as 'real' Americans. Bhabha's response (in track 2) is to assert that this is not **his** view (notice his repetition of the verb *say* in "I'm (not) saying..."), but that the source of the way black Americans are viewed today is an objective, historical fact; and in doing so, he is clearly rejecting Caroline Quinn's implied interpretation of his illocutionary stance in his first turn.

Inferring Intended Interactional Moves and Acts

Occasionally, speakers and their addressee(s) disengage themselves from the discourse which they are creating, to establish metadiscursively what the relation is between their adjacent moves. This occurs in the 'second' track, then, in Clark's (1996) terms. When this happens, we get an explicit view of how the discourse participants are interpreting each other's utterances (see also Cameron, 2001: 116). An example occurred during a discussion about the Devil in another edition of *Start the Week* (April 22, 1996). Here, Melvyn Bragg (MB) is picking up on Peter Stanford's characterization of the use of 'the Devil' by the medieval Church as a means of social control:

MB: yes – the interesting thing is that was it already coercive an' repressive – or did it actually call out something that's in people anyway – I mean the way you put it is that this is an authority this is a Church behaving as the Church behaved in many many different ways – in great ways an' in wicked ways – but this is a Church behaving in a very authoritarian way – in saying "you will follow us – or we will er – we will – get you and we've got the man to get you – he's called 'the Devil'" – but – isn't there something else there – isn't it a recognition of what's part of human nature and it was a BRILLIANT metaphor – just as Christianity is full

of brilliant metaphors as to what human nature is about so – .hhh it's more positive in a way than [what you're saying]

PS: [well – well] it wouldn't have worked would it – un unless they were actually tapping into something that people wanted to believe – and if you think about it =

MB: = so you're agreeing =

PS: = I'm agreeing – but if you think about the – concept of evil...

Melvyn Bragg, in his first turn, is objecting to what he sees as a one-sided view of the status of the Devil in the medieval Church, according to Peter Stanford's earlier characterization: he is taking the view that, rather than 'imposing' the Devil on believers in an authoritarian manner, the medieval Church more intelligently used the Devil as a metaphor for something that it recognized as already being part of human nature. Given that it is the former view which Bragg understands Stanford to be adopting, he clearly expects him to disagree with his objection. Yet Stanford's response is in conformity with this 'objection,' so it cannot count as a 'disagreement.' As soon as Bragg realizes this, he interrupts Stanford's response and asks him (via a declarative request) for confirmation of this interpretation. Stanford then immediately gives it by repeating the 'agreement' statement, then moves straight on to a development of the main point he had begun making at the point of interruption. This is achieved via a repetition of the actual words of his preceding final utterance (with the conjunction *and* replaced by the adversative *but*): ... *and if you think about it* ... This is clear evidence of the 'two-track' structure of textual development, as argued by Clark (1996), since the final conjunct of the preinterrupted segment by Peter Stanford is repeated virtually verbatim immediately after the interruption. This indicates that the primary, 'official business' track has not in fact been interrupted, but that it is the secondary, metadiscursive one which contained the interruption.

Conclusion

As Clark (1996) in particular emphasizes throughout his book, discourse is a joint endeavor, not the individual responsibility of the speaker, where the addressee has a merely passive role in decoding his or her utterances. The textual record (verbal content of the utterances as well as meaningful gestures, prosody, and phatic and other vocalizations) underdetermines the discourse which the participants are jointly constructing as the text unfolds in a particular context. The discourse constructed at any given point in this unfolding is a tentative, probabilistic affair, and not only is it subject to continual modification

in terms of updating as each new utterance is encountered, but the immediately preceding discourse at a given point may also be revised and reconstructed retroactively, as a function of a subsequent discourse act or move. This may occur when a participant, encountering another's reaction to what he or she is attempting to say, realizes the latter has misunderstood his or her propositional content or illocutionary stance or the nature of his or her move (see the *Start the Week* examples above). In triggering this process of updating, revision and (re)negotiation, discourse particles, vocal and visual gestures, pausing and prosody generally, all take on a crucial significance. The dual-track structure of textualization suggested by Clark (1996) makes possible this parallel management of the discharge of 'official discourse business' (track 1) on the one hand, and the signaling of discourse organization (track 2) on the other.

Use Theories of Meaning

G Martí, ICREA and Universitat de Barcelona, Barcelona, Spain

© 2006 Elsevier Ltd. All rights reserved.

Traditional theories of meaning of the kind proposed by Frege, Russell, and the early Wittgenstein take to heart the idea that language is a system of symbols whose essential role is to **state** or to **represent** the goings on of the world and the mind. From the point of view of a traditional, or representationalist, approach to meaning, the fundamental area of inquiry about language and its significance has to do with the connection between linguistic items and the things they stand for or represent, things or facts. That is why two of the main focal points of traditional theories of meaning are the theory of

reference – the exploration of the bond that ties expressions in a language to things in the world – and the theory of propositions – the discussion of the form and the constitution of what is expressed by utterances of sentences and their role in the determination of truth or falsity. So-called use theories of meaning can be best seen as reactions to the fundamental tenets of traditional theories: whereas traditional theories focus on what language represents and how it represents it, use theories search for the key to meaning in actual usage and linguistic practice.

The first strong appeal to use in the theory of meaning appeared in print in 1950, in P. F. Strawson's article 'On Referring.' Strawson's article is meant to be primarily a critical response to the analysis of sentences containing definite descriptions proposed by Bertrand Russell in his seminal paper

'On Denoting.' The merits or demerits of Strawson's specific objections to Russell's theory of descriptions will not be addressed here. The important point for our purposes is rather the positive outlook on meaning that Strawson's remarks suggest. In criticizing Russell, Strawson (1971: 9) contends that "to talk about the meaning of an expression or sentence [is to talk about] the rules, habits, conventions governing its correct use, on all occasions to refer or to assert". Although rather programmatic in character, Strawson's remarks point towards a conception of the significance of linguistic expressions that departs radically from the Frege–Russell–early Wittgenstein approach for, according to Strawson, neither the things that terms stand for, as Russell and Wittgenstein would have it, nor the conceptual material associated with expressions – the sense – that in turn determines what those expressions stand for, as Frege would have it, constitute appropriate answers to the question 'What is the meaning of X?' On the contrary: "to give the meaning of an expression is to give general directions for its use" (Strawson, 1971: 9).

Traditional theories of meaning, with their emphasis on reference and propositions, leave out of the realm of semantic inquiry a host of expressions whose significance cannot be doubted. For what does 'hello' refer to? What proposition do we express, what fragment of the world do we represent, when we say 'hello'? If we do express a proposition, under which conditions is it true or false? Unlike traditional theories, use theories of meaning would explain the meaning of 'hello' and similar expressions by appeal to the rules and conventions that indicate their appropriate use. But it is not only expressions such as 'hello,' 'ouch,' or 'pardon' that, according to use theorists, are left behind by traditional approaches. J. L. Austin argued that this is so for a class of sentences, which he characterized as 'performative,' that look grammatically like any other subject-predicate or subject-verb-object sentence that we use to represent a fragment of the world, such as 'It is raining' or 'The train is late.' We use the latter to tell the way things are and consequently when we utter them we say something true or something false. Performative utterances, on the other hand, do not state or represent the way things are. When we utter a performative, Austin argues, we certainly say something significant, yet it is neither true nor false. The uses of sentences that Austin is thinking of are utterances of, for instance, 'I name this ship *Queen Elizabeth*,' 'I do [take this man to be my husband],' 'I promise to be at the party,' 'I apologize.' According to Austin what all these sentences have in common is that by uttering one of them we do not report or describe a state of affairs, an event or an action. Uttering one

of those sentences is actually **performing** an action. Uttering a performative is a speech act. By saying 'I do,' as Austin (1961: 235) puts it, "I am not reporting on a marriage, I am indulging in it". Because utterances of performatives do not function like statements, the question of truth or falsity does not arise with regard to them. However, there are, Austin points out, ways in which performatives can succeed or fail. For instance, if the utterer does not have the authority to give a name to a ship, her utterance of 'I name this ship *Queen Elizabeth*' does not succeed in performing the intended action. For an utterance of a performative to be satisfactory some felicity conditions must be in place.

It is tempting to think that Austin is highlighting a phenomenon circumscribed to a well-delimited class of utterances, and that for the vast majority of natural language sentences the traditional representational picture applies smoothly. That is not so: what Austin is proposing is not just a specific treatment of a peculiar phenomenon but rather a different conception of meaningfulness. On Austin's view, statements, as much as performatives, are essentially speech acts and are therefore subject to similar conditions of adequacy and success. Suppose we utter a statement such as 'John's children are all very polite' and John has no children. According to Austin, the situation as regards that statement parallels a performative utterance such as 'I promise I will sell you this piece of land' when the piece of land in question does not exist. In the latter case we would say that the sale is void; and in the former case we should say that the statement is void also. Both performatives and statements are subject to the question 'Is it in order?' If the answer is negative, the performance fails. And if the answer is positive, then both performatives and statements are subject to further questions of felicity. Those questions may take different forms depending on the type of speech act: if it is a warning, the question is whether it was justified; if it is a piece of advice, the question is whether it was sound; if it is a statement, the question is whether it was true; in every case, although in different forms, those questions "can only be decided by considering how the content ... is related in some way to fact ... we do require to assess at least a great many performative utterances in a general dimension of correspondence with fact" (Austin, 1961: 250). In this way Austin (1961: 251) takes statements "off their pedestal" and offers a uniform picture of meaning that appeals essentially to our usage of expressions to do things.

Among use theorists we cannot forget Ludwig Wittgenstein, the coiner of the motto 'meaning is use.' In the first part of the *Philosophical Investigations*,

completed in 1945 although not published until 1953, Wittgenstein reacts strongly against the traditional conception of meaning. In fact, Wittgenstein is reacting against his own earlier views presented in the *Tractatus Logico-Philosophicus*. Wittgenstein's account of meaning in the *Tractatus*, with its characterization of the proposition as a picture of a fragment of the world, is the paramount example of a traditional representationalist approach. In the *Investigations*, by contrast, Wittgenstein rejects the explanatory project of Frege and Russell: neither the Fregean senses that are supposed to determine the objects expressions refer to, nor the things that on Russell's (and the *Tractatus*'s) approach are directly and conventionally associated with signs, give life and significance to language: only its use gives meaning to a sign.

To understand the kind of practice we engage in when we use a language as members of a speakers' community, Wittgenstein appeals to the metaphor of playing a game. For Wittgenstein, learning a language, like playing tennis, consists in becoming competent at a rule-governed practice. It does not consist in explicitly learning the rules, having them, so to speak, written in one's mind; being able to play tennis, or being able to speak and understand a language consists in being proficient at doing something according to the rules.

Different use-oriented approaches to meaning criticize the traditionalist stance for disregarding the fact that language is a tool that we use to do things, that speaking and understanding a language is a matter of engaging in a practice, and that, consequently, the key to meaning is to be found in the way language users employ language. But how radical the departure from the traditional stance is depends on how the motto 'meaning is use' is interpreted. On the one hand it may be interpreted as a claim about what gives expressions the meaning they have. The appeal to use is then a reminder that languages are social institutions and that it is by virtue of usage that expressions are connected to their meanings. From this point of view, it is not inappropriate to say, for instance, that by virtue of its use, the word 'dog' means a certain concept or that its meaning consists in naming a species. So interpreted, the claim that meaning is use is fundamentally presemantic, it is not a claim about what constitutes the meaning of expressions. So conceived, use theories of meaning are not opposed in essence to traditional theories, although by stressing the meaning-conferring role of use they expand the horizons of the traditional stance, for they make room in semantic theory for expressions whose meaning cannot be cashed out in terms of what and how

they represent objects or states of affairs, and they do not disregard aspects of meaning that are not truth conditional.

A more radical way of interpreting the claim that meaning is use is as a semantic claim, i.e., a claim about what constitutes the meaning of linguistic expressions. From this point of view there is nothing over and above the way an expression is used that can qualify as its meaning. Use is not just what makes an expression have a meaning; it is **all there is** to meaning. Some varieties of deflationism take this stance. Thus, for instance, in Horwich (1998: 6) we read: "The meaning property of a word reduces [to] ... the property that every use of the word is explained in terms of the fact that we accept certain specified sentences containing it."

The radical interpretation of the claim that meaning is use faces a number of objections. Here I will focus on only two general challenges (for discussion, see Horwich, 1998). First, it may be argued that the idea that use determines the meaning of an expression puts the cart before the horse. Intuitively there is a distinction to be drawn between correct or incorrect usage. No matter how pervasive the use of 'irregardless' is, it is an incorrect expression. The very idea of incorrect, but extended, use seems to entail that it is because expressions do have a meaning, over and above the way in which they are used, that we can talk about correct or incorrect usage. Meaning determines (correct) use and not vice versa, so it seems that the claim that meaning is constituted by use has difficulties accounting for the normative aspect of meaning.

Second, the idea that all there is to the meaning of an expression is its use does not leave room for what appears to be a legitimate possibility: a speaker may be competent in the use of an expression, she may know the situations in which it is appropriate to use it and how to react to uses of it, and yet she may not know the meaning of the expression in question. The possibility is, in fact, less far fetched than it appears. Consider the case of Helen Keller: blind and deaf from an early age, she explains in her autobiography how she and her family had developed a rather good system of symbols to communicate their needs and wishes: when she wanted bread, she made a sign, when she wanted ice cream, she made another sign. Her mother had ways to tell Helen what she needed, and Helen would go and get it for her: Helen had mastered the use of a system of symbols. Nevertheless, when she was seven her teacher, Miss Sullivan, once spelled on Helen's hand the sign for water while Helen felt water with her other hand, and that was the moment that she describes as "learning the key to

all language.” What could she possibly have discovered that she didn’t know before? It surely was not how to use the sign ‘water’ but rather, and quite simply, that ‘water’ stands for water. Now, it may be argued that learning that ‘water’ can be used to refer to water is indeed learning something new about the use of ‘water.’ But then it would appear that even from the point of view of use theories of meaning we need to be sensitive to the fact that expressions represent things and that it is the relation between words and things that makes it possible for us to talk about the world.

Use versus Mention

C Spencer, Howard University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Generally, the distinction between using something and mentioning it is completely straightforward. For instance, there is all the difference in the world between mentioning, or talking about, a lawn mower, and using it to mow the lawn. Yet the distinction can engender some confusion when it comes to mental and linguistic representations, and this is what philosophers and linguists have in mind when they talk about the use/mention distinction. The distinction between mentioning a word, picture, or mental representation, and using it to communicate or entertain a thought is best illustrated by example. Sentence (1) uses the word ‘Boston,’ and sentence (2) mentions it.

- (1) Fred is from Boston.
- (2) ‘Boston’ has two syllables.

Philosophers customarily put a word (or complex expression) inside quotation marks, to form its ‘quote name,’ if they want to mention it instead of using it, as in (2). Linguists, in contrast, typically use italics, labeled bracketing trees, or a phonetic alphabet to mention an expression, as in (3a–c).

- (3a) *Boston* has two syllables.
- (3b) [_{NP} Boston] has two syllables.
- (3c) bɒs tən has two syllables.

An advantage of the philosopher’s convention is that we may easily form the quote name of a quote name

simply by enclosing the quote name itself in quotation marks, as in (4):

- (4) “‘Boston’” is the name of a word, not a city.

We can also mention an expression without using any of these devices, as in (5) and (6).

- (5) The first line of Gray’s *Elegy* states a proposition.
- (6) Samuel Clemens’s pen name is derived from a riverboat driver’s call.

Example (5) uses an expression, ‘the first line of Gray’s *Elegy*,’ to mention the linguistic expression it denotes, namely, ‘The curfew tolls the knell of parting day.’ Similarly in (6), the expression ‘Samuel Clemens’s pen name’ is used to mention another linguistic expression, namely ‘Mark Twain.’

When we talk more systematically about a particular language, as we do in describing its syntax or semantics, we observe the related distinction between object language and metalanguage. The object language is the language under discussion, and the metalanguage is the language we use to talk about the object language. In some cases, the object language and the metalanguage are different languages, as in (7), but the object language and the metalanguage can be the very same, as in (8).

- (7) ‘Le chien est sur la chaise’ is true if and only if the dog is on the chair.
- (8) ‘The dog is on the chair’ is true if and only if the dog is on the chair.

Sentences (7) and (8) mention sentences of the object language (enclosed within quotation marks).

The metalanguage, in both cases English, is the language used to state the truth condition of sentences in the object language.

Sentences that mention themselves, such as (9), can give rise to paradox.

(9) This sentence is false.

Sentence (9) appears to have the paradoxical property of expressing a truth if and only if it expresses a falsehood. Many sentences that mention themselves are innocent in this respect, such as (10):

(10) This sentence contains five words.

The paradox only arises for sentences that self-ascribe semantic properties such as truth or falsehood. A central project of a theory of truth is to resolve this paradox.

So far, the use/mention distinction seems easy to keep straight: How could someone confuse the name 'Boston' with the New England city itself? Yet philosophers sometimes charge one another with confusing use and mention of linguistic expressions. Such confusion typically results in mere obscurity, as it does in this passage from Leibniz, as translated by C. I. Lewis.

Two terms are the same if one can be substituted for the other without altering the truth of any statement. If we have A and B and A enters into some true proposition, and the substitution of B for A wherever it appears, results in a new proposition which is likewise true, and if this can be done for every such proposition, then A and B are said to be the same; and conversely, if A and B are the same, then they can be substituted for one another as I have said (Lewis, 1960: 291).

Richard Cartwright has suggested that the apparent use/mention confusion here makes it difficult to see exactly what Leibniz intended to say in this passage (Cartwright, 1971: 119). Perhaps Leibniz meant that A and B are the same if and only if **their names** can be intersubstituted into any statement without altering the truth value of the proposition that the statement expresses. If this was what he

meant, then in some places he should have **mentioned** the names of A and B rather than **using** them, as he in fact did.

In other cases, however, use/mention confusions may ground substantive philosophical mistakes. One such mistake is the familiar confusion of objects with our ideas of them. This mistake arises particularly for philosophically problematic entities such as the number three and Beethoven's Ninth Symphony. It is obvious that they are not concrete objects, but less obvious what else they could be. Since we clearly have ideas of these objects, some have suggested that we identify the objects themselves with our ideas of them. cursory reflection reveals that this suggestion cannot be correct, since these entities have properties that ideas could not have. Ideas, for instance, cannot be the cube root of 27 or played frequently by the Berlin Philharmonic. Plausibly, what lies behind this suggestion that objects like these are really ideas in our heads is a confusion of our mental representations of these objects with the objects themselves. Like the confusion of the word 'Boston' with the city of Boston, this is a straightforward confusion of use with mention.

V

Voloshinov, Valentin Nikolaevich

S O'Neill, University of Oklahoma, Norman, OK, USA

© 2006 Elsevier Ltd. All rights reserved.

Valentin Nikolaevich Voloshinov was born in Saint Petersburg, Russia, on June 30, 1895. Though he originally set out to study law, entering Saint Petersburg University in 1913, material circumstances forced him to leave in 1917, before finishing his degree. For the next several years, Voloshinov held a series of teaching stints, serving as a piano instructor for the People's Education Department, for instance, before meeting up with fellow teachers Bakhtin and Medvedev, who were all working in Vitebsk in 1920. The three intellectuals stayed in close contact throughout the 1920s, engaging in lively discussions about language, politics, philosophy, and literature, and forming what is today known as the Bakhtin Circle.

Determined to continue his training as a linguist, Voloshinov returned to his native Saint Petersburg (then renamed Petrograd), where he completed his studies in ethnology and linguistics, finishing his university degree in 1924. The following year, he accepted a position as a research assistant at Saint Petersburg University, in the newly formed Institute for the Comparative History of the Literatures and Languages of the West and East, where he continued as a postgraduate student in 1926, later becoming a research fellow after completing his studies in 1929. Starting in 1932, Voloshinov taught sociology and art at the Herzen Pedagogical Institute, a position he kept until 1934, when poor health forced him to end his professional life. Voloshinov succumbed to the ravages of tuberculosis in 1936, ending a brief but brilliant career that has only recently gained public recognition.

Voloshinov is best known for his sophisticated work on language ideology, a concept he initially drew from Marxist philosophy, with its strong focus on the political ramifications of public consciousness. As Voloshinov came to argue in his seminal work, *Marxism and the philosophy of language* (1929), public discourses are constructed in verbal encounters,

in which speakers negotiate worldview through dialogic exchanges, often defending or even countering the dominant ideologies expressed elsewhere in a society. Of course, the whole framework is reminiscent of the dialogic approach to language that Voloshinov's friend, Bakhtin, articulated. For this reason, many scholars are inclined to attribute the writings signed by Voloshinov and published under his name solely to Bakhtin. The issue of authorship remains open, though many now entertain the possibility that the influence was mutual. In this article, the works published under Voloshinov's name are treated as his alone.

Deeply dissatisfied with the linguistics of his day, Voloshinov sought to develop a new school rooted in social interaction rather than in abstract structural characteristics, such as phonetics, lexicon, and grammar, which were increasingly being studied for their own sake. Voloshinov argued that linguists had adopted an inappropriate methodology derived from the study of dead languages, in which the utterance was, of necessity, removed from its original social setting as an isolated, monologic byproduct. Yet in a living language the utterance is central to the construction of meaning, which derives as much from the social context as it does from structural traits, such as word order or grammatical categories.

For Voloshinov, the meaning of an utterance is always based on a specific 'theme,' or a common stock of assumptions shared by participants, one that is generally rooted in the unrepeatable circumstances of the encounter. From this perspective, a word or grammatical concept takes on subtle new shades of meaning every time it is uttered. Consider the use of the pronoun 'we' in the framing of the American constitution, where the reference once excluded both women and slaves, who were systematically barred from participating in the government for some time to come. Or consider the racial use of the color terms 'black' and 'white' before the civil rights movement of the 1960s. Ordinary words can propagate powerful social ideologies for specific groups in specific times. Yet Voloshinov also maintained that linguistic concepts retain a core ideological neutrality

and potential multivalence, allowing them to potentially convey any ideology or even mean different things to different groups at different times. Hence, the expression 'we the people' no longer excludes women, though it did in early America. In actual use, Voloshinov argued linguistic concepts always carry an evaluative, ideologically charged sense – meaning that they always convey specific perspectives, often with strong political overtones.

Where Saussurean linguists posited an idealized speaker–hearer with a perfect command of relatively homogeneous grammar and vocabulary, Voloshinov argued that meaning is always changing through use, and speakers differ profoundly in their knowledge, stylistic preferences, or deployment of grammatical rules. Where Saussurean linguists represented communication with arrows passing from an active speaker to a passive addressee, who merely decodes the speech by relying on the conventional meanings of linguistic concepts, Voloshinov argued that communication was in fact a two-way street or 'double-sided act,' in which the receiver also plays an active role in shaping meaning, anticipating contemporary speech act theory. For Voloshinov, the listener also plays a role in shaping the exchange, whose outcome neither party ever fully anticipates. Finally, where the Saussurean model of the invariant linguistic sign relegated the messy issue of change to the diachronic realm, where its source still remained mysterious, Voloshinov regarded change as a byproduct of dialogue, or the constant negotiation of perspective in actual language use, where structure and meaning are always undergoing subtle revision.

Because his new school of linguistics was based on the ideologically charged utterance, Voloshinov devoted a whole section of *Marxism and the philosophy of language* to problems of 'reported speech.' For, in actual practice, speakers spend a great deal of time quoting or repeating the words of other speakers. Also, if the linguist analyzes speech, the discipline had better develop a methodology for accurately

reporting the utterance, without ignoring the author's role in shaping meaning assigned to speakers. One approach is to maintain sharp boundaries between authorial and reported speech, clearly separating the two voices with quotation marks or subordinate clauses, for instance. In contrast to this painstaking 'linear' method, Voloshinov notes the existence of the 'pictorial' approach, in which the author takes the liberty of interspersing the reported speech with commentaries and replies, as in literature. Another tendency is to capture the content, if not the style, a approach Voloshinov dubbed the 'referent analyzing' approach, as opposed to the contrasting 'texture analyzing' approach, in which the author strives to capture the tone and feel of the reported speech.

Vygotskij, Lev Semenovich

S A Romashko, Russian Academy of Sciences and Moscow State University, Moscow, Russia

© 2006 Elsevier Ltd. All rights reserved.

Born in Byelorussia, Lev Semenovich Vygotskiĭ studied at Moscow University from 1913 to 1917, gaining experience in a wide range of disciplines from

medicine to law. His most vivid interest of this time concerned art and literature, and some of the elements of his early art criticism were later incorporated into his main psychological work. Returning to Byelorussia, Vygotskiĭ worked in Gomel as teacher and lecturer in different institutions, where he tried to reform the ways of teaching according to the new postrevolutionary situation. His interest in the

process of knowledge transmission and assimilation led him more and more to the problems of psychology and symbolic interaction.

In 1924, Vygotskiĭ was invited to work at the Institute of Psychology in Moscow, where he started intensive research in different branches of psychology, psychophysiology, and related fields. His dissertation on psychology of art (1925, published only in 1965) recapitulated his early ideas of art (mainly literary) criticism, combined with new methodology of 'psychological reaction,' and tried to detect the objective principles of aesthetic function (as a specific 'aesthetic reaction') without reduction to other psychological mechanisms. After a short time, his life was overshadowed by two dangerous circumstances: mortal disease (he had tuberculosis) and growing political suppression of the Stalinist totalitarian regime transformed the last years of Vygotskiĭ's life into a race against time. He took every real opportunity to realize his ideas, working in different institutions in and outside Moscow. Vygotskiĭ prepared in 10 years almost 200 publications. On the other hand, this hectic situation of approaching different subjects in his passionate investigations caused serious hermeneutic problems for those who studied his theories later: it is clear that Vygotskiĭ's position was changing even during this short time, but there is no simple key to determine the development and general features of his varying positions.

Vygotskiĭ was one of the first people to detect the importance of aphasia for both psychology and linguistics, pointing to the connection between neurophysiology and early structuralism in linguistics (phonology as a pilot model for the study of speech disorders). These ideas were continued later by his disciple, A. R. Luria. Together with Luria and other adherents, Vygotskiĭ founded the so-called 'cultural-historical school' in psychology. The 'cultural-historical' approach tried to show the way out of a situation which Vygotskiĭ detected in the middle of the 1920s as a 'crisis in psychology.' The idea was to go beyond the physiology of I. S. Pavlov and create a more substantial and adequate base for an objective theory of the human mind, which should be a real Marxist psychology in Vygotskiĭ's opinion. The early stages of psychic development were always the main concern of Vygotskiĭ. Together with Luria, he wrote a book on the emerging mind, considering ape, 'primitive' man, and child as different aspects of early stages of psychic functions (Luria and Vygotskiĭ, 1930). Vygotskiĭ stressed the crucial role of language and other semiotic means as a specific universal instrument in human behavior, providing the basic condition for the development of the human mind and consciousness. Considering the early stages of language,

Vygotskiĭ showed that these 'primitive' forms of linguistic activity are really very rich in possibilities, required by corresponding sociocultural situations.

Vygotskiĭ's main work, *Thought and language* (1934), was published shortly after his death. This book unified different aspects of Vygotskiĭ's work around the main point of his search: the dynamic functional interconnection of language and thought. Both are considered not as static entities, but as activities in a sociocultural context. Both are complex realities with an inner history: the language in its written form is another functional realization of linguistic activity, different from the oral speech and reflecting another stage of cultural (educational) development. The most original part of Vygotskiĭ's theory was the idea of inner speech as mediating dynamic mechanism between thought and language. Considering child development, Vygotskiĭ criticized J. Piaget, stressing that even the earliest stages of linguistic behavior are a part of social interaction: children are mastering language skills during their interaction with the social environment and as a part of practical mastering of reality. Children's way to thought and language is a way from external to inner behavioral activity.

Early death interrupted Vygotskiĭ's investigations, but saved him from very probable political repression. A few years after his death, his ideas were totally banned from the official Soviet science. Only in the post-Stalinist period were Vygotskiĭ's ideas rediscovered in the Soviet Union, and they became more and more known in the West. The publication of *Psychology of art* (1965) attracted additional interest to Vygotskiĭ, showing a lesser-known part of his work. During the following decades, Vygotskiĭ's heritage produced wide discussions in psychology and linguistics (especially psycholinguistics). His work was considered from different positions: the psycholinguists and neurolinguists considered him as a founder of their disciplines; the structuralists and representatives of semiotics found in Vygotskiĭ their forerunner; and the cognitivists classified him as a 'precognitivist.' However, his systematic and functional approach to the old problem of thought and language, his ideas about linguistic behavior remain a productive avenue for linguistic analysis.

Whorf, Benjamin Lee

T C Christy, University of North Alabama, Florence, AL, USA

© 2006 Elsevier Ltd. All rights reserved.

A self-taught linguist, who also studied American Indian linguistics under Edward Sapir at Yale, Benjamin Lee Whorf is best known for his work in developing the ‘Sapir-Whorf’ or ‘linguistic relativity hypothesis,’ the central claim of which – that the structures of language, in addition to providing a vehicle for the expression of thought, also shape thought by casting it in the mold of language-specific patternings – echoes views advanced in the early 19th century by Wilhelm von Humboldt in his writings on linguistic diversity. In Whorf’s words, “... the world is presented in a kaleidoscopic flux of impressions which has to be organized by our minds – and this means largely by the linguistic systems in our minds” (Carroll, 1956: 213). Whorf’s study of American Indian languages – for example Uto-Aztecan (Aztec and, in particular, Hopi) and Mayan (Maya) – convinced him that the grammatical categories of languages structure both perception and conceptualization. He developed this hypothesis principally in his papers “Grammatical categories,” “Some verbal categories of Hopi,” and “The relation of habitual thought and behavior to language” (1939), all of which are reprinted, along with other of Whorf’s published and unpublished writings, by John Carroll (1956), who, in his introduction to this volume, provided much useful biographical information. The linguistic relativity hypothesis is notoriously difficult to corroborate or refute, with empirical evidence, involving, as it does, the calibration of linguistic with cultural and cognitive considerations. The limited evidence produced to date – for example, cross-linguistic surveys of color terminology (Berlin and Kay, 1969) – has both undermined the strong version of the hypothesis, according to which language determines and limits, as opposed to influencing, the

architecture of cognition, and called attention to the influence of other factors. While the focus of the linguistic relativity hypothesis is squarely on the relation of language to thought, clearly biological constraints on perception, as well as cultural influences, are also involved. The difficulties attending ascertaining where one influence begins and the other ends have contributed to the still largely indeterminate status of the linguistic relativity hypothesis. Moreover, the sheer fact that translation from one language to another is possible diminishes the likelihood that languages differ by entire categories of thought. Last, linguistic universals, by definition, also put an upward limit on the reach of linguistic relativity.

Wierzbicka, Anna

M Miskovic-Lukovic, Institut für
Fremdsprachenphilologien, Oldenburg, Germany

© 2006 Elsevier Ltd. All rights reserved.

Anna Wierzbicka, the founder and leading exponent of natural semantic metalanguage (NSM) theory, is internationally known for her work in semantics, syntax, pragmatics, and cross-cultural linguistics. Her theory combines a radically universalist approach, that human concepts are innate, with a relativist approach, that ordinary languages have different semantic systems representing culture-specific configurations of universal semantic primitives.

Wierzbicka was born in 1938 in Warsaw, Poland. Early in her childhood she evinced a keen interest in language, playing word games with her father and writing poetry. A Polish Catholic, who lived in her homeland until 1972, she had little sympathy for Communist ideology.

Wierzbicka's academic career began at the University of Warsaw. After receiving a Ph.D. from the Polish Academy of Sciences, she continued postdoctoral studies in Moscow in 1965. In 1966, she spent a year studying and researching at MIT. In 1972, she settled in Canberra, Australia. Wierzbicka is a professor of linguistics at the Australian National University. She is a Fellow of the Australian Academy of the Humanities and Australian Academy of Social Sciences and has also been awarded the Humboldt Research Prize for Foreign Scholars in Humanities.

Her principal publications include *Semantic primitives* (1972), *Lingua mentalis: the semantics of natural language* (1980a), *The case for surface case* (1980b), *Lexicography and conceptual analysis* (1985), *English speech act verbs: a semantic dictionary* (1987), *The semantics of grammar* (1988), *Cross-cultural pragmatics: the semantics of human interaction* (1991), *Semantics, culture and cognition: universal human concepts in culture-specific configurations* (1992), *Semantics: primes and universals* (1996), *Understanding cultures through their key words: English, Russian, Polish, German, Japanese* (1997), *Emotions across languages and cultures: diversity and universals* (1999), and *What did Jesus mean? Explaining the Sermon on the Mount and the parables in simple and universal human concepts* (2001).

Wierzbicka's scholarship is characterized by the search for 'semantic primes,' a small core of irreducible universal meanings, which can be found as words, bound morphemes, or phrasemes in all languages. The theory rests on the following premises: semantic analysis must be conducted in natural language;

complex meanings can be stated in terms of simpler ones (reductive paraphrase); the NSMs of all languages are isomorphic. The NSM approach to meaning is intensional – semantic primes are conceptual but they are not abstract, they correspond to word meanings in ordinary language. Over the period of 30 years of extensive empirical, cross-linguistic investigations, Wierzbicka and her colleagues have collected a set of about 60 lexical universals (e.g., A LONG TIME, DO, GOOD, PEOPLE, etc.). This 'mini-lexicon' of semantic primes and the manner of their combination constitute a metalanguage that is supposed to have the same expressive power as any ordinary language. The metalanguage has a wide range of applications, such as intercultural communication, language acquisition and teaching, language typology, legal semantics, and lexicography. Additionally, it serves as a basis for an emergent theory of cultural scripts, considered as shared interpretive background, and used for the description of the 'verbal culture' of any society.

Wittgenstein, Ludwig Josef Johann

W A de Pater and P Swiggers, Katholieke Universiteit Leuven, Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Ludwig Wittgenstein, one of the most influential philosophers and, in terms of general impact, thinkers of modern times, was born in Vienna on April 26, 1889. He was one of eight children in a mixed Catholic and Protestant (earlier Jewish) family, which intensively participated in the cultural and economic life of Vienna at the turn of the 19th/20th century, characterized by cosmopolitanism, by a suffocating bourgeois mentality (which also explains the rise of psychoanalytic treatments in society of that time), and by an unequalled theater and music life. Wittgenstein's father, after having been a wool merchant, had established himself in Vienna as the director of a large steel company, and the family enjoyed a luxurious life, albeit overshadowed by oppressing and depressing paternal authoritarianism. The children were all endowed with artistic, technical, and intellectual skills, but seem to have experienced problems in psychological development and social adaptation; three of Ludwig's brothers committed suicide, and Ludwig's own life was characterized by constant imbalance in developing his own personality and in adapting to life in society. Wittgenstein received his first education in his parents' palatial home in Vienna, and showed remarkable technical skills (as a young boy, for example, he constructed a sewing machine). He was sent to a Gymnasium in Linz (1903–1906), and then to the Technische Hochschule in Charlottenburg (Berlin), where he stayed for two years. In 1908 he went to study at the University of Manchester in England, where he started doing aeronautical research; he designed a jet reaction engine and a propeller. Until then his interests had been in physics and in technology, but seeing how much mathematics was involved in both, he soon became interested in the philosophical foundations of mathematics. Having heard of the existence of Russell's *Principles of mathematics* (1903), Wittgenstein established contact with Russell and, on the occasion of a trip to Germany, with Frege. In the academic year 1911–1912 he enrolled at Cambridge University in

order to study with Russell, on whom he left a deep impression. While at Cambridge he laid the basis of his logical views; he also spent much time performing music and doing experiments on rhythm in music.

During World War I, Wittgenstein was an officer in the Austrian army; in November 1918 he was taken prisoner by Italian troops and was held captive for some months in Italy. During wartime he had been systematizing his ideas on logic and philosophy; the resulting manuscript was sent to Russell (who discussed it with Wittgenstein in Holland in December 1919) and was published (in German) in 1921. This *Logisch-philosophische Abhandlung* (containing 526 decimally ordered short paragraphs) was subsequently translated into English and was published in 1922 with an introduction by Russell, under the title *Tractatus logico-philosophicus*. The book, which was the only philosophical book Wittgenstein published during his lifetime (in 1926 he also published a children's dictionary for use in primary school), is an important contribution to philosophy, and more particularly to the theory of logical atomism, which Russell had been developing for some years and which holds that there are only atomic facts (the connections made through words like 'and,' 'or,' 'if ... then' are only logical manipulations), and that these can be analyzed exhaustively in terms of particulars, properties, and relations. Written in the form of a list of theses or statements, the *Tractatus* proposes a 'picture theory': our sentences have meaning because (and only insofar as) they are pictures of reality. Reality consists of facts (*Tatsachen*), and facts exist by virtue of being realized states of affairs (i.e., reality, or 'the world,' is everything that is the case); states of affairs (*Sachverhalte*) are nothing else but configurations of things (*Gegenstände; Dinge; Sachen*). Our thoughts (thinking has a 'factual' content, contrary to imagination or illusion) are, in Wittgenstein's terms, logical pictures of facts; to convey our thoughts to others, we need to express them in sentences (combinations of words, generally seen as names by Wittgenstein), which can be perceived by the senses.

The world view and the philosophy of language contained in the *Tractatus* have radical consequences: if language only has meaning when it pictures reality, then the statements of logic and mathematics

(which deal with how language works/should work) have no 'meaning' (one cannot make a picture of how a picture represents reality), and so the propositions of the *Tractatus* itself are devoid of meaning, senseless (*sinnlos*). However, Wittgenstein recognized the importance, or usefulness, of these propositions: they serve as 'elucidations,' enabling us to make the distinction between what has meaning and what does not. Wittgenstein even stressed the importance of a 'mystical' dimension concerning our life, our religious beliefs, our ethical convictions, our aesthetic experiences; the crucial point for Wittgenstein is that this mystical dimension should not be presented as 'facts' (we deal here with 'problems of life'). Sentences that try to express this dimension are nonsensical (*unsinnig*): they do not picture facts, nor do they try to make explicit the way our language works. To say that the world exists is nonsensical, since its existence is not a fact in the world. But it shows itself, viz. in the existence of language. Language, indeed, is the totality of meaningful, i.e., fact-picturing sentences, and thus the limits of our language are the limits of our world. But when all has been said that can be said, we have not even touched upon the problems of life: they belong to the realm (the most important realm!) of the nonsensical, of what cannot be said but only shows itself.

Wittgenstein's views on meaning were endorsed by the members of the *Wiener Kreis* (Vienna Circle, the birthplace of neopositivism) – although Wittgenstein felt that nobody, not even Russell, had understood and grasped the contents and the (deeper, ethical) meaning of the *Tractatus*, and although the picture-theory was not adopted by the *Kreis*. The book was submitted in June 1929 as a Ph.D. dissertation at Cambridge, where Wittgenstein had returned after World War I and a few wandering years (in 1920 he was a gardener in Klosterneuberg, between 1920 and 1926 he was a schoolteacher in the Austrian villages of Trattenbach, Puchberg, and Otterthal, and after that he became again a gardener in the monastery of Hütteldorf). The years 1927 and 1928 were spent in Vienna, where he designed a mansion (which he wanted 'free from all decoration and marked by a severe exactitude in measure and proportion') for his sister Margarete, and had regular contacts with members of the *Wiener Kreis*, especially Moritz Schlick, Friedrich Waismann, and Herbert Feigl. But Wittgenstein's 'return' to philosophy seems to have been caused by a lecture given in Vienna in March 1928 by L. Brouwer on the foundations of mathematics. Brouwer's theory of intuitionism in mathematics strongly appealed to Wittgenstein, who realized that mathematics is essentially a constructive activity, and that meaning lies in the recovery of the

process of construction (of a proof, of a theorem, etc.), and not in the discovery of a (*a priori*) given truth. Wittgenstein's *Tractatus* already contained a number of statements about mathematics as a method (and not as a doctrine) and about the importance of 'making clear' what is meant (= elucidation), and presented a method (viz. truth tables) for calculating the truth or falsity of a proposition that is a truth-function of other propositions, but the picture-theory of meaning and the view of language as being essentially a nomenclature (a set of names) – both central ideas of the book – were of course hardly compatible with intuitionism and constructivism. It would take Wittgenstein several years to rebuild his philosophy, and to develop a completely new (and very original) theory of meaning. This new theory constituted the core of the philosophy of the 'later Wittgenstein,' as distinct from the 'younger Wittgenstein,' author of the *Tractatus*. Whether there is a radical break or a gradual transition between the two periods is a matter of dispute among Wittgenstein scholars, with some defending the discontinuity thesis and others the continuity view; a somewhat subversive, though not inaccurate, way to reconcile both views is to say that Wittgenstein remained interested in the ideas expounded in the *Tractatus*, but (mainly) in order to show how wrong they were.

The philosophy of the 'later Wittgenstein' was elaborated at Cambridge, where Wittgenstein started to lecture in January 1930, and where he had contact with Russell, G. E. Moore, and F. P. Ramsey. Wittgenstein taught there between 1930 and 1936, then spent one year living as a solitary in Norway, and returned to Cambridge in 1937, where he later succeeded Moore in the chair of philosophy. During World War II, Wittgenstein, by then a British citizen (since 1938), took the side of the allied troops and worked at Guy's Hospital in London and subsequently in the Royal Victoria Infirmary in Newcastle. He resumed his teaching at Cambridge in 1944, but took an early retirement in 1947. He went to live in Ireland and then spent some time in the United States. In late 1949 he was diagnosed with cancer, and from that time on he prepared himself for his death. He lived briefly in Vienna and in Oxford, then went to Norway, before spending the last months of his life in Cambridge, in the home of his physician. He died on April 29, 1951, leaving behind a mass of unpublished materials (notebooks, lecture notes, unfinished book manuscripts, letters), much of which was published (and translated) by his students and friends after his death.

Wittgenstein's Cambridge years were marked by intense philosophical activity, by a considerable amount of academic teaching, and by the shift from

a dogmatic and axiomatic formulation (so typical of the *Tractatus*) to a dialogue form of philosophizing, with more questions raised than answers given. The later Wittgenstein also covered a wide variety of topics, and most prominently beyond the domains of logic and mathematics (although in the years 1937–1944 he wrote down his remarks on the foundations of mathematics): he reflected upon (ordinary) language, psychology, ethics, aesthetics, and religion, and dealt with the general problems of meaning, knowledge, belief, and social behavior. During the first years after his return to Cambridge, Wittgenstein was particularly interested in verification as the (constructivist) method of establishing the meaning of propositions (in the *Tractatus* he had not dealt with the role of verification); but as soon as the early 1930s he realized that the demand of verification should not be kept too strict, and that there is also meaning beyond (or behind) what can be verified. Wittgenstein completely abandoned the picture-theory and the concept of meaning as an (ideal) object, i.e., precisely those principles in virtue of which he could be seen as an adherent of neopositivism or of logical atomism; most of his work from the 1930s and 1940s can be seen as a criticism of the views of the *Wiener Kreis* and of Russell's philosophy (in his conversations with Schlick and Waismann of the years 1929–1932, the differences separating Wittgenstein from the *Wiener Kreis* are clearly expressed). From the early 1930s on, when he wrote the manuscript of his *Philosophical grammar* (the first part of which deals with 'meaning,' 'rules,' and 'language use') and dictated the contents of *The blue and brown books*, Wittgenstein stressed the manifold forms, functions, and uses of language. The best-known work from the later Wittgenstein's philosophical legacy, to which most often reference is made, is the *Philosophical investigations* (written, with an interruption in 1945–1947, between 1936 and 1949; this text, one of the most finished among Wittgenstein's manuscripts, was posthumously published in 1953). The philosophy – or the philosophical itinerary – formulated in this (not very systematically structured) book implies a dynamic view of language, seen not as a collection of names but as a toolkit containing 'countless' kinds of uses of words and sentences and a changing set of 'language-games' (*Sprachspiele*), such as describing, reporting, guessing, translating, thanking, greeting, and telling jokes (the 'language-games' were previously dealt with in *The blue book*). The essential question to ask then is not 'What is the meaning of sentence S?', but 'How is S used here?' and 'How does S fit within a larger set of sentences?' Asking these questions is inquiring after the meaning of activities, and only in this way are we able to get a view of the 'grammar

rules' of each game. The answer (or multiple answers) to these questions also require(s) that we consider sentences (and the words contained in them) in their 'surroundings' (in Wittgenstein's terminology). Here we see the basic difference from the doctrine of the *Tractatus*: meaning is not shown by the sentence taken on itself, but it becomes (partly) manifest in each of the uses to which a sentence is put; also, whereas in the *Tractatus* Wittgenstein held that any proposition presupposes all other propositions (because of their 'common essence'), in his later work he emphasizes the idea that we only hit upon segments of the whole of language. A very elliptical summary of the later Wittgenstein's theory of meaning is therefore 'Meaning is use' (use/employment/application; the German terms are *Gebrauch/Verwendung/Anwendung*). The implications of this dynamic and 'perspectivist' view on meaning have been drawn by Wittgenstein's commentators, who have been assembling, comparing, and confronting the dispersed remarks, questions, and musings – on meaning, knowledge, belief, and (especially in the second part of the *Philosophical investigations*) emotion, sensation, remembering – found in the posthumously published materials, in view of the fact that Wittgenstein abstained from giving definitions of the key terms in his later philosophy. The 'language-games' that can be performed in using language show intricate relationships and partly overlapping, partly diverging features (in their formal aspects, their functions, their purposes): Wittgenstein spoke of 'family resemblances,' which justify the general designation 'language-game' without implying an 'essential' unity (language functions in multiple ways); the same vague conception applies to the structure of language, which Wittgenstein saw as irregularly patterned (the structure of language is compared to the plan of an old town, with irregular streets and squares, dead alleys, etc.).

The later Wittgenstein proposed a philosophy that is basically an activity of constant questioning, doubting, observing, and relativizing; it is a message of caution against doctrinarism, (hasty) generalization, speculation, one-sided approaches, and also 'bewitchment' (by language, by so-called evidence, by theories): the aim is 'to show the fly the way out of the fly-bottle' (overgeneralization and one-sidedness lead us into the bottle). It is therefore characterized by a search to determine criteria (or at least one good criterion) in order to find out something about states of the mind (belief, thought, will, hope, etc.) while avoiding the recourse to introspection (in his *Remarks on the foundations of mathematics* Wittgenstein stressed the foundational role of mathematical operations). To understand the 'grammar

rules' of the language-games, it is necessary to observe the uses of sentences that function within the various games, and this requires contextual and interpersonal observation: we cannot make abstraction of the 'surroundings' in which words and sentences are used, and language-games (and thus also language) are a social reality, i.e., language-games are (integrated as) *forms of life* (the relationship between language and experience figures prominently in Wittgenstein's *Remarks on colour*). Wittgenstein denied the possibility of 'private rules' and therefore of a private language: rules functioning within a game are necessarily shared rules (they exist only because there is agreement about them), and therefore there are no rules that would be followed by only one individual, since following a rule consists in 'doing the same.' The issue of private rules, in connection with linguistic behavior and linguistic competence, has become a main topic of post-Wittgensteinian debate between scholars holding an empiricist view of language and those holding a rationalist, innatist view of language; Wittgenstein himself rejected both flat behaviorism and unqualified mentalism, because of their one-sidedness and being out of touch with linguistic reality. The ultimate argument for such a view lies of course in a person's (linguistic) history: we have acquired language by learning how sentences are used in what types of contexts (the language games are part of 'our natural history,' as Wittgenstein put it).

In the two main phases of his philosophical career Wittgenstein exerted great influence upon contemporary philosophical conceptions: whereas his *Tractatus* was a source of inspiration for neopositivists (although Wittgenstein's 'deeper' message was radically opposed to the doctrine of logical positivism, as well as to Russell's logical atomism), his later work inspired British analytical philosophers (although the later Wittgenstein's method was not so much one of analysis, but rather one of questioning and of patiently describing, i.e., of recovering the 'uses-in-context'). A similar twofold impact on linguistic work can be observed: whereas the doctrine of the *Tractatus* has inspired work on the categorical structure of language as being, ideally, a nomenclature with syntactic rules for combining names (thus justifying a monolithic type of analysis), the ideas put forward in the *Philosophical investigations* (and in the other writings of the 1930s and 1940s) have inspired scholars favoring a pragmaticist view of meaning and an ethnographic study of language (thus justifying a multifunctional and combinatory or polythetic approach, integrating meaning, knowledge, and action; Wittgenstein's *On certainty* offers a nice illustration of such an approach). Beyond that,

Wittgenstein's life and works, also when misunderstood or indirectly known, have inspired psychologists (Wittgenstein lectured on 'philosophical psychology,' especially on the 'body-mind problem,' and had written important *Remarks on the philosophy of psychology*), anthropologists, educationists, moralists, and artists.

Word and Image

T van Leeuwen, Cardiff University, Cardiff, UK

© 2006 Elsevier Ltd. All rights reserved.

Since the 1970s, the analysis of written text has played an increasingly important role in applied linguistics, for instance in areas such as education, the analysis of media texts, and, more recently, Internet communication and critical discourse analysis. Gradually it has become evident that it was no longer viable to focus only on the verbal aspects of such texts, not only because they use images as an integral part of the text but also because visual composition (layout), color, and typography play an increasingly important role in structuring them, through the use of space, typography (including special typographic signs such as bullet points), and color coding. As a result, linguistic or linguistically inspired methods for integrating the analysis of the linguistic and non-linguistic aspects of written text have begun to emerge.

Paris School Structuralism

The first linguistically inspired approach to the analysis of images and image–text relations was that of 1960s Paris School structuralist semiotics.

Using media texts such as advertisements and news photographs as his data, Roland Barthes' (1977) work in this area focused on the concepts of 'denotation' and 'connotation.' In defining these concepts, he drew on the work of Hjelmslev, who had argued that different ways of expressing the same concept can have different meanings, if only because the same concept can be expressed in different languages, and speakers therefore never simply communicate a concept but communicate their country of origin as well. Extending Hjelmslev's approach to the analysis of images, Barthes proposed to analyze images in terms of two layers of meaning, denotation, the layer of 'what, or who, is represented here' and connotation, the layer of 'what ideas and values are expressed through what is represented, and through the way in

which it is represented.' In other words, much as in John Stuart Mill's original use of the two terms, denotation was interpreted as reference to concrete people, places, and things, and connotation as reference to abstract concepts. Although this is often misunderstood, for Barthes, connotations were not subjective associations but "culturally accepted inducers of ideas" (1977: 23). In a key example (1973: 116), originally from 1959, he described an image on the cover of *Paris-Match* that showed a young black soldier saluting the French flag. The denotation is what is shown: 'a black soldier salutes the French flag.' The connotation is a more abstract concept, conveying a late colonialist ideology, "a purposeful mixture of Frenchness and militariness," as Barthes described it (1973: 116).

In a later essay, Barthes specified key signifiers of connotation: objects (e.g., the flag in the above example) and poses (e.g., the salute). There is, he wrote, an unwritten 'dictionary' of poses that "form ready-made elements of signification" (1977: 22). He added that connotation can also come about through the style of artwork or through techniques of photography such as "framing, distance, lighting, focus, speed": "An inventory needs to be made of these techniques, but only insofar as each of them has a corresponding signified of connotation sufficiently constant to allow its incorporation in a cultural lexicon of technical 'effects'" (1977: 23).

Barthes' approach to image-text relations focused on the concepts of 'anchorage' and 'relay.' In the case of 'anchorage,' words 'elucidate' pictures, selecting specific aspects from the meaning potential of the image: "[T]he text directs the reader through the signifieds of the image, causing him to avoid some and receive others" and "remote-controls him towards a meaning chosen in advance" (1977: 39). In other words, anchorage is a conjunctive relation of specification between word and image in which words specify the meaning of images that, in themselves, are 'polysemous,' open to a range of possible interpretations. In the case of 'relay,' "text and image stand in a complementary relationship." They are both "fragments of a more general syntagm" (1977: 41). As an example, he cites comic strips, in which pictures show the speaker(s) and the context, and words their speech. The two concepts are thus close to what Halliday (1994) calls 'elaboration' and 'extension,' except that 'elaboration' includes not just 'specification' but also a range of elaborative relations, including rephrasing, summarizing, exemplifying, and so on.

Barthes's concepts have been widely adopted in media studies. A well-known example of their application to political discourse is Stuart Hall's (1973) article 'The determination of news photographs,'

which shows how captions can interpret relatively ambiguous shots of politicians according to newspapers' editorial policies.

Christian Metz, in his work of the 1960s, applied linguistic concepts to the study of film. Having initially attempted to find the filmic equivalents of phonological and syntactic form classes, he concluded that film shots are not "doubly articulated" and that the structure of film shots cannot be compared to the structure of sentences. Film shots simply reproduce what was in front of the camera, relaying the meanings of action, dress, and so on. Larger textual structures, however, can be studied in a linguistic spirit. In his most widely quoted paper of the period (1974) he outlined a 'syntagmatics' of film that was, in effect, a systematic overview of the conjunctive relations that can exist between the shots and scenes of a film, and that built on constructivist theories of editing by 1920s filmmakers and theorists such as Pudovkin, Eisenstein, and Timoshenko (cf. van Leeuwen, 1991). These conjunctive relations are for the most part temporal, although temporality in film involves more than simple sequentiality and includes simultaneity ('parallel editing'), flashbacks, and flash forwards. In addition, there are 'descriptive' syntagms, where a place is 'described,' not by showing it in a single shot, but through a scene showing a series of 'detail' shots, and comparative syntagms, in which shots with similar or contrasting content are edited together. This is a form of editing introduced by constructivist filmmakers to make specific political points, for example, by intercutting a scene showing workers with the slaughtering of a bull to depict the destruction of the spirit of the working class by capitalism. Metz's syntagmatics has been picked up again in linguistically inspired approaches to film (van Leeuwen, 1991; Iedema, 2001).

In the same period, Jacques Durand (1983) wrote an influential article presenting a structural classification of the rhetorical figures that had been described in the classical literature on rhetoric, and demonstrating that they can all be applied, not just to words, but also to images. His examples were taken from advertisements. Thus, a visual oxymoron might show a basket of strawberries in the snow, a visual chiasmus a picture of a father and a son wearing each other's clothes and carrying each other's newspapers, a visual metonymy a block of ice instead of a refrigerator (in an advertisement for refrigerators), and so on.

I have discussed only three examples here, but during the 1960s and early 1970s many other similar studies were published, mostly in the French journal *Communications*.

Although I will restrict myself here to approaches based on linguistics, the study of word and image has

also played a vital role in iconography, a branch of art history occupying itself with representation and meaning in works of art. Although iconographers do not develop descriptions of ‘visual languages’ and focus on the work of individual artists, or on specific themes or schools, their work offers important clues for the study of word and image, especially where it concerns artworks based on mythological and Biblical texts (Schapiro, 1973 is an example; Van Leeuwen, 2001 discusses iconography in more detail).

Functional Linguistics

A more recent linguistically inspired approach to the study of word and image is strongly influenced by the functional linguistics of Michael Halliday (1978, 1994).

Kress and van Leeuwen (1996) base their approach on Halliday’s three metafunctions (1978): the ideational function of constructing representations of the world; the interpersonal function of creating relations between the participants in acts of communication; and the textual function of marshalling individual representations-cum-interactions into coherent texts that can be recognized as types. They also follow Halliday in linking specific systems of visual grammar to specific metafunctions. While Barthes’ approach had been ‘lexical,’ based on the denotative and connotative meanings of the individual people, places, objects, and poses depicted in images, Kress and van Leeuwen’s approach is ‘grammatical,’ focusing on the way visual composition creates meaningful relations between the people, places, and things in images, not only on the broader textual level, but also within individual images or ‘shots.’

According to Kress and van Leeuwen, the ideational function is visually realized by a grammar of transitivity, which comprises two types of syntagm, the narrative and the conceptual. In narrative syntagms, the ‘participants’ are realized by ‘volumes’ and the ‘processes’ by ‘vectors.’ The formal terms (‘volume’ and ‘vector’) are derived from the art theorist Arnheim (1974), the functional terms (‘participant’ and ‘process’) from Halliday. In other words, word and image can realize the same semantic functions, but in different ways – in language, participants are typically realized by nominal groups, and processes by verbal groups.

To take an example, Eddie Adams’s famous photograph of a summary execution on the streets of Saigon (Figure 1) contains two participants, Nguyen Ngoc Loan, the South Vietnamese officer who points the gun, and the Vietcong suspect who is about to die. The two participants are the main volumes, clearly demarcated against a somewhat out-of-focus

Figure 1 Execution (after Eddie Adams’s photograph of 1968).

background, and Loan’s arm, holding the gun, forms a vector connecting the two. In this syntagm the two participants have different functional roles. The participant from whom the vector emanates (here Loan) is the Actor; the participant at whom the vector is directed (the Vietcong suspect) is the Goal (the terms are again taken from Halliday). As there are two participants, the syntagm is transitive. An intransitive action syntagm would contain only the Actor and the vector.

The same relationship can also be realized in diagrams. The participants are then boxes with words in them, or diagrammatic pictures, while the vector is realized by an arrow. Eye lines, which connect participants through the direction of the look of one of the participants, form a different kind of vector, and hence realize a different kind of process, a ‘reaction’ rather than an action. Reactions, too, can either be transitive or intransitive.

Conceptual syntagms realize a process, not through vectors, but through some kind of spatial configuration. Classification syntagms, for instance, realize a ‘kind of’ relation between participants by means of a composition in which the participants are symmetrically arranged on the picture space, are of equal size (even when in reality they are not), and have the same distance between them and the same horizontal and vertical orientation. This suggests that they all belong to the same category. In such syntagms, the relation between the participants is represented as a stable and quasipermanent relation, rather than in terms of an action or event.

Images can also realize interpersonal meaning through (1) size of frame, which can bring depicted elements closer to the viewer or keep them at a distance; (2) angles, which can confront viewers directly with depicted participants or represent the relation as more oblique, and which can place viewers either above or below depicted participants; and (3) through the gaze of depicted participants, which can

address viewers directly and so realize a symbolic 'demand' (for sympathy, respect, sexual interest, etc., depending on the accompanying facial expressions and/or gestures) or address the viewer indirectly and so create a barrier between the represented world and the word of the viewer.

Textual meanings are visually realized by three aspects of composition: the placement of the elements of a composition in the visual space (top or bottom, left or right, center or margin); the relative salience of the elements; and the degree to which the elements are separated from each other by frame lines, empty space, or other visual devices. These aspects of visual structuring apply not only to the elements of pictures but also to the elements of layouts (e.g., headlines, pictures, blocks of text), so that analysis can reveal, for instance, the relative salience of text and image and the way they are compositionally related.

Kress and van Leeuwen's approach therefore allows an integrated analysis of the visual and linguistic aspects of written text. The analyst can ask, for instance, which participant is visually the Actor and which participant is linguistically, or discover that the image addresses the viewer directly, while the text does not.

O'Toole's theory of visual communication (1994) also takes its inspiration from the linguistics of Halliday and is in many ways complementary to Kress and van Leeuwen's approach. Like Kress and van Leeuwen, O'Toole takes Halliday's metafunctions as his point of departure and assigns specific visual systems to specific metafunctions. But unlike Kress and van Leeuwen, he also introduces rank, analyzing visual communication as building 'figures' from 'members,' 'episodes' from 'figures,' and 'pictures' from 'episodes' in the same way that language builds words from morphemes, groups from words, clauses from groups, and clause complexes from clauses. Specific systems of visual grammar realize each of the three metafunctions at each of the four ranks. 'Representational' meanings, for instance, may be realized by 'actions and events' at the rank of picture, 'groups and subactions' at the rank of episode, individual 'characters' at the rank of figure, and 'parts of the body' at the rank of member. Perspective is one of the systems that realize what O'Toole calls 'modal' meanings at the level of picture, 'relative prominence' one of the systems that realize it at the rank of episode, 'gaze' one of the systems that realize it at the rank of figure, and so on.

The functional approach to the study of word and image has been applied in a number of fields and has also been extended to film (van Leeuwen, 1996; Iedema, 2001) and new media (Lemke, 2002;

Kress, 2003). The journal *Visual Communication* regularly publishes papers by scholars working with this approach.

Ethnomethodology and Conversation Analysis

The relation between word and image (or, more broadly, the visual) has also been approached from the perspectives of ethnomethodology and conversation analysis. Charles Goodwin (e.g., 2001), Heath (e.g., 1986), and others have focused on the way professional discourses interpret images and other visual phenomena in quite specific ways that often differ markedly from commonsense interpretations. In the court proceedings following the police beating of Rodney King, for instance (Goodwin, 2001: 175–178), the crucial evidence was a videotape that actually showed police officers beating King. Yet the police officers were acquitted, at least in the first trial, because of the testimony of an expert witness who interpreted the video in terms of professional police codes for determining aggressive intent. Specific movements were interpreted as being at the start of an "aggression spectrum" (2001: 176):

Witness: It is starting to be [aggressive]
 (pointing) This foot is laying flat
 (pointing) There's starting to be a bend
 (pointing) this leg
 (pointing) in his butt
 (pointing) the buttocks area has started to rise
 which would put us at the beginning of our
 spectrum again

Goodwin and others have also argued for the inclusion of the gaze and other visual signifiers (e.g., pointing) in conversation analysis transcripts, showing that without those signifiers it is often impossible to determine what drives the specific moves that conversation analysts are interested in (e.g., restarts, repairs). This can be of crucial importance in areas such as the study of medical interaction.

Typography

Even though typography is perhaps the most obvious visual aspect of written language, it has until recently been ignored by linguists. Crystal is an exception (1998: 7):

The explication of printed language needs the expertise of both typographers and linguists, in order to provide a complete description of its forms and structures and a satisfactory explanation of its functions and affects.

New technologies such as the word processor have made typographic expression available to everyone, and as a result linguists also are becoming more aware of it (e.g., Graddol, 1996). Overall, however, they have not gone much beyond categories that are well established in the typographical literature, such as the difference between the classic serif and the modern sans serif and between text and display fonts, the former requiring, in the first place, legibility and clarity, the latter leaving more space for typographic expression (e.g., in relation to brand names, titles, logos, and so on). Walker's book on the subject (2001), in the series 'Language and social life,' describes many of the rules and prescriptions that govern everyday uses of typography, although not in a specifically linguistic framework. Van Leeuwen (2005) used the concepts of connotation and metaphor to discuss typographic meaning and in more recent work (in press) argued for the semiotization of the 'distinctive features' of typography, thus both adapting and extending Jakobson and Halle's 'distinctive feature theory' of phonology. He argues that the distinctive features of letter forms (e.g., weight, roundedness versus angularity, regularity versus irregularity) lend themselves more easily to metaphoric extension than whole letter forms. Roundedness, for instance, can, depending on the context, signify organic, natural, feminine, and so on. As a given font combines several distinctive features, several such metaphors may resonate in it.

Many contemporary typographers are interested in blurring the boundaries between images and letter forms by 'iconizing' either the letter forms themselves and/or the way they are arranged on lines and pages. In this way they regain a connection that had been lost in the development of the alphabet. Typography is also increasingly multimodal, using not only the elements of letter forms, bowls, stems, ascenders, descenders, serifs, and so on, but also color, texture, 3-dimensionality, and movement. Journals such as *Visible Language*, *Information Design Journal*, and *Visual Communication* regularly publish in the area.

Conclusion

Linguists have only recently begun to pay attention to the many forms of visual expression and structuring in written texts. As the importance of visual communication grows in many areas, including, for instance, education, science, workplace literacy, and global communication, the study of word and image is likely to undergo rapid growth in the near future. As Kress has said (2003: 168), the major task facing us now:

... is to imagine the characteristics of a theory which can account for the processes of making meaning in the environments of multimodal representation in multimeditated communication ... Such a theory will represent a decisive move away from the assumptions of mainstream theories of the last century about meaning, language, and learning.

Writing and Cognition

M Torrance, Staffordshire University,
Stoke-on-Trent, UK

This article provides a brief overview of research exploring the cognitive processes associated with text production by human writers, focusing on the handwritten or keyboarded production of coherent, multi-sentence texts. Currently, written production, in this sense, is less well understood than either text comprehension or spoken production.

Text production is a skill that typically starts to develop in children at around the age of six or seven and as a result of extensive specific instruction. This contrasts with the ability to participate in spoken dialogue, which develops much earlier and largely through exposure to parents' speech. A good stepping-off point for describing the cognitive psychology of text production is to ask what mental processing is required to produce text over and above that which is required for participation in dialogue. First, in most contexts and particularly those typically studied by researchers, writers become aware of the need to write something before they have a definite message to communicate. Planning what to say is, therefore, a major feature of most writing tasks. Second, writers need to be able to maintain and develop meaning across a number of sentences. Turn taking in dialogue both allows immediate feedback on the comprehensibility of an utterance and provides a stream of cues that aid decisions about what to say next. In the absence of an interlocutor writers must find alternative strategies for maintaining coherence. Third, unlike speech, writing requires the planning and execution of letter shapes (or keystrokes) and the retrieval of word spellings. Fourth, one benefit that writing has over speech is that it is possible to review and edit output before it reaches its audience. Text production is therefore necessarily complex, requiring coordination of high-level processes for determining content and structure, and low-level processes associated with producing words on the page.

A chapter by Hayes and Flower (1980) is frequently cited as providing the first general cognitive

theory of text production. Their model characterized writing as a problem-solving activity: Writers identify one or more goals for their text, described in terms of the effect that the text will have upon intended readers, and then work backwards from this to identify plans of action by which these goals might be achieved. Hayes and Flower described three processes: planning (determination of content and structure), translating (the process by which this structure is realized as full text), and revising (checking that the text does, in fact, fulfill communicative goals). Studies in which writers are asked to think aloud while producing text suggest that each of these three processes is available to the writer at any point during production. Although planning is more likely to occur near the start of a writing task, and revision towards the end, producing a document typically entails multiple plan-translate-review cycles. Hayes and Flower provided hypotheses about how planning, translating, and revision processes might function, although the problem-solving framework in which these were couched has typically not been adopted in subsequent research. Many researchers have, however, used Hayes and Flower's terminology.

Planning Content

How writers determine content (a process called 'generating' in the Hayes and Flower model) varies with task, and with writer maturity and motivation. In all cases, however, generating will entail cued retrieval from long-term memory (LTM). Writers temporarily hold relevant concepts active in working memory. These concepts act as memory probes and activation spreads from them to related concepts in LTM. Concepts retrieved in this way are then either written down in note form for later use or translated directly into text. Studies exploring the time course of the planning process suggest that propositions tend to be retrieved in repeated bursts of activity interspersed with lulls during which there is no retrieval. Activity during these lulls is thought to be associated, at least in part, with refreshing the probe.

Differences among writers, and particularly developmental differences, are likely to be associated with

the ways in which probes are constructed. Novice writers and writers with low motivation may refresh probe content more or less randomly, or simply rely on immediately available cues – exact words or phrases contained within the text of the writing assignment, for example. Content generated in this way will tend to follow a path of least resistance through a writer's existing knowledge about a topic. Bereiter and Scardamalia (1987) described this stream-of-consciousness approach to generating content as 'knowledge telling.' They contrast this with 'knowledge transforming,' an approach that is available only to more experienced writers. Knowledge transforming involves, in Bereiter and Scardamalia's terms, a dialectic between discourse space and content space: instead of probing memory with whatever cues are most readily available, probe selection is constrained by rhetorical considerations. Content is thus determined not just by a writer's knowledge of the topic but also by the effect that they wish to have on their intended readers. One result of knowledge transforming is that the first idea that occurs to a writer is unlikely to become the main focus of their text. Another is that writers may, as a direct result of writing about a topic, discover new ideas or arguments.

Planning Rhetorical Structure

Writers need not only to retrieve relevant propositions but also to tie these together into a coherent whole. Hayes and Flower identified a specific sub-process dedicated to organizing content prior to its realization as full text. This does not appear to be essential, however. Some writers, and particularly novices, add ideas into the text in more or less the order in which they are retrieved. Where writers do engage in deliberate rhetorical structuring prior to producing full text, they often then deviate from this structure during translation.

Beyond these general observations, however, the processes by which coherent structure is achieved are poorly understood. Some recent research has taken as a starting point the assumption that coherent text comprises a hierarchy of text spans linked by rhetorical relations. Using an analytic procedure called PISA (procedure for incremental structural analysis), an approach similar to rhetorical structure theory, Schilperoord and coworkers have demonstrated an association between text structure and writers' patterns of pausing: writers tend to pause for longer at rhetorically defined text span boundaries, and this effect is independent of the pausing associated with orthographic features such as sentence and paragraph boundaries. Developmentally,

more experienced writers tend to produce texts with deeper and more branched structures. This may be because as writers mature, their discourse knowledge – the range of possible rhetorical relations that they have at their command – expands. Alternatively, this effect may be due to developmental increases in short-term storage capability. Producing a highly branched rhetorical structure is likely to involve keeping a greater number of propositions active in short-term memory than is necessary when producing less complex structures.

Translating Plans into Text

A central concern of recent research has been the extent to which processing low-level tasks – developing syntax, and spelling and transcribing words – interferes with retrieving and organizing content. In a series of experiments exploring verbal memory in children, Bourdin and Fayol have demonstrated that written recall is substantially poorer than spoken recall. This effect is largely absent in adults, suggesting that as spelling and handwriting are practiced they make fewer demands on higher-level cognitive mechanisms. However, even in adults there are some contexts in which transcription and content retrieval compete for cognitive resources. Mature writers may reduce the probability of conflict by adopting two writing-specific memory management techniques. Several researchers have suggested that experienced writers construct retrieval structures that allow very rapid access to content stored in long-term memory. This strategy, termed 'long-term working memory,' liberates cognitive resources during translation by reducing the information that must be held in short-term memory. Another widely used strategy for reducing the possibility of cognitive overload involves dividing up the writing process into discrete subtasks by, for example, outlining content and structure in note form before producing full text. In experimental contexts this outlining tends to result in the production of higher-quality text. Arguably, this is because separating out planning and translation processes removes the possibility that they will compete for the same resources.

Reviewing and Revision

Most writers in most contexts spend time reading back over the text that they have written. For example, in one study 15-year-olds producing short argumentative essays spent, on average, 20% of their total writing time in some sort of reviewing activity. Reviewing, however, takes a variety of forms. Writers regularly pause and read back over the two or three

sentences they have just written. This local reviewing appears to serve more to cue in new sentences than to edit or repair existing text. Curiously, preventing competent writers from reading what they write (by, for example, turning the computer screen off while competent typists word process) does not typically affect the quality of the final text. There appears to be a trade-off between the benefits of knowing (and possibly editing) what has just been written, and the detrimental effect of the additional load that local reviewing imposes on short-term memory.

The extent to which full read-evaluate-edit cycles occur varies considerably across writers and tasks, with typically very few occurrences in novices' writing. Little is known about the cognitive processes that underlie evaluation, although there is a general assumption that editing is prompted by the writers perceiving dissonance between their intended message and the message that they infer from their text. This dissonance may occur because the writer lacks the necessary lexical or rhetorical knowledge to convert their preverbal message into text, although there is some evidence that suggests that writers are only able to detect those problems that they have the necessary knowledge to repair. Another cause of dissonance may arise because writing results not only in an external expression of a writer's existing ideas about a topic but often also in an internal realignment or development of those ideas within the writer's mind. Thus, when a writer experiences dissonance when reading back over earlier paragraphs, this may not be because at the time of writing the writer's translation of ideas into text was inaccurate. It may instead be because the writer's thinking has since moved on. Strategically, it is possible to capitalize on this dynamic interaction between text and thought by deliberately producing multiple rough drafts, allowing meaning to develop with the text. This technique is sometimes called 'free' or 'generative' writing.

SUBJECT INDEX

NOTES

The index is arranged in set-out style with a maximum of three levels of heading. Major discussion of a subject is indicated by bold page numbers. Page numbers suffixed by T and F refer to Tables and Figures respectively. *vs.* indicates a comparison.

Cross-reference terms in italics are general cross-references, or refer to subentry terms within the main entry (the main entry is not repeated to save space). Readers are also advised to refer to the end of each article for additional cross-references - not all of these cross-references have been included in the index cross-references.

This index is in letter-by-letter order, whereby hyphens and spaces within index headings are ignored in the alphabetization. Prefixes and terms in parentheses are excluded from the initial alphabetization.

To assist the user, specific languages have main entries in **bold**. To save space in the index, subjects specific to a language (e.g. morphology, syntax) are found as subentries under the language and not the subject. Cross references to the specific subjects (e.g. syntax, phonetics) are assumed and not explicit.
